<ul class="itemize mark-bullet"> Apply the distort0r effect, setting the first two double parameters: <pre class="example-preformatted">frei0r=filter_name=distort0r:filter_params=0.5|0.01 </pre>

Apply the colordistance effect, taking a color as the first parameter: <pre class="example-preformatted">frei0r=colordistance:0.2/0.3/0.4 frei0r=colordistance:violet frei0r=colordistance:0x112233 </pre>

Apply the perspective effect, specifying the top left and top right image positions: <pre class="example-preformatted">frei0r=perspective:0.2/0.2|0.8/0.2 </pre>

For more information, see http://frei0r.dyne.org <h4 class="subsection">39.107.2 Commands# TOC</h4>

This filter supports the <samp class="option">filter_params</samp> option as commands. <h3 class="section">39.108 fspp# TOC</h3>

Apply fast and simple postprocessing. It is a faster version of spp. It splits (I)DCT into horizontal/vertical passes. Unlike the simple post- processing filter, one of them is performed once per block, not per pixel. This allows for much higher speed. The filter accepts the following options: <dl class="table"> <dt><samp class="option">quality</samp></dt> <dd> Set quality. This option defines the number of levels for averaging. It accepts an integer in the range 4-5. Default value is <code class="code">4</code>. </dd> <dt><samp class="option">qp</samp></dt> <dd> Force a constant quantization parameter. It accepts an integer in range 0-63. If not set, the filter will use the QP from the video stream (if available). </dd> <dt><samp class="option">strength</samp></dt> <dd> Set filter strength. It accepts an integer in range -15 to 32. Lower values mean more details but also more artifacts, while higher values make the image smoother but also blurrier. Default value is <code class="code">0</code> − PSNR optimal. </dd> <dt><samp class="option">use_bframe_qp</samp></dt> <dd> Enable the use of the QP from the B-Frames if set to <code

class=”code”>1</code>. Using this option may cause flicker since the B-Frames have often larger QP. Default is <code class=”code”>0</code> (not enabled). </dd> </dl>

 <h3 class=”section”>39.109 fsync# TOC</h3>

Synchronize video frames with an external mapping from a file. For each input PTS given in the map file it either drops or creates as many frames as necessary to recreate the sequence of output frames given in the map file. This filter is useful to recreate the output frames of a framerate conversion by the fps filter, recorded into a map file using the ffmpeg option <code class=”code”>-stats_mux_pre</code>, and do further processing to the corresponding frames e.g. quality comparison. Each line of the map file must contain three items per input frame, the input PTS (decimal), the output PTS (decimal) and the output TIMEBASE (decimal/decimal), separated by a space. This file format corresponds to the output of <code class=”code”>-stats_mux_pre_fmt="{ptsi} {pts} {tb}"</code>. The filter assumes the map file is sorted by increasing input PTS. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>file, f</samp></dt> <dd> The filename of the map file to be used. </dd> </dl>

Example: <pre class=”example-preformatted”># Convert a video to 25 fps and record a MAP_FILE file with the default format of this filter ffmpeg -i INPUT -vf fps=fps=25 -stats_mux_pre MAP_FILE -stats_mux_pre_fmt "{ptsi} {pts} {tb}" OUTPUT

Sort MAP_FILE by increasing input PTS sort -n MAP_FILE

Use INPUT, OUTPUT and the MAP_FILE from above to compare the corresponding frames in INPUT and OUTPUT via SSIM ffmpeg -i INPUT -i OUTPUT -filter_complex '[0:v]fsync=file=MAP_FILE[ref];[1:v][ref]ssim' -f null - </pre>

 <h3 class=”section”>39.110 gainmap# TOC</h3>

Compute an HDR gain map from two renditions of the same image, as defined by ISO 21496-1. The first input is the base rendition (typically SDR), and the second input is the alternate rendition (typically HDR). Both must have the same dimensions. Outputs a gain map, as either ‘<samp class=”samp”>gbrpf32</samp>’ or ‘<samp class=”samp”>grayf32</samp>’ depending on the

chosen <samp class="option">mode</samp>. <dl class="table"> <dt><samp class="option">mode</samp></dt> <dd> Controls what quantity the gain map is computed against. The accepted values are: <dl class="table"> <dt>‘<samp class="samp">rgb</samp>’</dt> <dd> One gain map channel per component. </dd> <dt>‘<samp class="samp">luma</samp>’</dt> <dd> A single gain map channel, computed from the luma. </dd> <dt>‘<samp class="samp">maxrgb</samp>’</dt> <dd> A single gain map channel, computed from ‘<samp class="samp">max(R, G, B)</samp>’. </dd> </dl>

Default is ‘<samp class="samp">rgb</samp>’. </dd> <dt><samp class="option">colorspace</samp></dt> <dd> Chooses which colorspace to compute the gain map in. The accepted values are: <dl class="table"> <dt>‘<samp class="samp">base</samp>’</dt> <dd> The base rendition’s colorspace. </dd> <dt>‘<samp class="samp">alternate</samp>’</dt> <dd> The alternate rendition’s colorspace. </dd> </dl>

Default is ‘<samp class="samp">base</samp>’. </dd> <dt><samp class="option">min</samp></dt> <dt><samp class="option">max</samp></dt> <dd> Bounds on the encoded gain (log2). If unspecified, these will be measured from the frame. </dd> <dt><samp class="option">gamma</samp></dt> <dd> Encoding gamma of the resulting gain map. If unspecified, this will be optimized for the frame in question. Setting this to <code class="code">1.0</code> will produce a linear gain map, which may be more efficient in some applications. </dd> <dt><samp class="option">base_offset</samp></dt> <dt><samp class="option">alt_offset</samp></dt> <dd> Offset to prevent numerical instability near zero. Both default to <code class="code">1/64</code>. </dd> <dt><samp class="option">base_nits</samp></dt> <dt><samp class="option">alt_nits</samp></dt> <dd> Override the reference luminance of the input, in nits. If unspecified, uses the values from the input metadata. </dd> </dl>

The <code class="code">gainmap</code> filter also supports the framesync options. <h4 class="subsection">39.110.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Compute a gain map between an SDR and an HDR version of the same image: <pre class="example-preformatted">ffmpeg -i $sdr -i $hdr -filter_complex "[0:v][1:v]gainmap" $out </pre>

 <h3 class="section">39.111 gblur<span class="pull-

right”>#
TOC</h3>

Apply Gaussian blur filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sigma</samp></dt>
<dd> Set horizontal sigma, standard deviation of Gaussian blur. Default is <code class=”code”>0.5</code>. </dd> <dt><samp class=”option”>steps</samp></dt> <dd> Set number of steps for Gaussian approximation. Default is <code class=”code”>1</code>. </dd> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes to filter. By default all planes are filtered. </dd> <dt><samp class=”option”>sigmaV</samp></dt> <dd> Set vertical sigma, if negative it will be same as <code class=”code”>sigma</code>. Default is <code class=”code”>-1</code>. </dd> </dl>

 <h4 class=”subsection”>39.111.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class=”section”>39.112 geq# TOC</h3>

Apply generic equation to each pixel. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>lum_expr, lum</samp></dt> <dd> Set the luma expression. </dd> <dt><samp class=”option”>cb_expr, cb</samp></dt>
<dd> Set the chrominance blue expression. </dd> <dt><samp class=”option”>cr_expr, cr</samp></dt> <dd> Set the chrominance red expression. </dd> <dt><samp class=”option”>alpha_expr, a</samp></dt> <dd> Set the alpha expression. </dd>
<dt><samp class=”option”>red_expr, r</samp></dt> <dd> Set the red expression. </dd> <dt><samp class=”option”>green_expr, g</samp></dt> <dd> Set the green expression. </dd>
<dt><samp class=”option”>blue_expr, b</samp></dt> <dd> Set the blue expression. </dd> </dl>

The colorspace is selected according to the specified options. If one of the <samp class=”option”>lum_expr</samp>, <samp class=”option”>cb_expr</samp>, or <samp class=”option”>cr_expr</samp> options is specified, the filter will automatically select a YCbCr colorspace. If one of the <samp class=”option”>red_expr</samp>, <samp class=”option”>green_expr</samp>, or <samp class=”option”>blue_expr</samp> options is specified, it will select an RGB colorspace. If one of the chrominance expression is not defined, it falls back on the other one. If no alpha expression is specified

it will evaluate to opaque value. If none of chrominance expressions are specified, they will evaluate to the luma expression. The expressions can use the following variables and functions: <dl class="table"> <dt><samp class="option">N</samp></dt> <dd> The sequential number of the filtered frame, starting from <code class="code">0</code>. </dd> <dt><samp class="option">X</samp></dt> <dt><samp class="option">Y</samp></dt> <dd> The coordinates of the current sample. </dd> <dt><samp class="option">W</samp></dt> <dt><samp class="option">H</samp></dt> <dd> The width and height of the image. </dd> <dt><samp class="option">SW</samp></dt> <dt><samp class="option">SH</samp></dt> <dd> Width and height scale depending on the currently filtered plane. It is the ratio between the corresponding luma plane number of pixels and the current plane ones. E.g. for YUV4:2:0 the values are <code class="code">1,1</code> for the luma plane, and <code class="code">0.5,0.5</code> for chroma planes. </dd> <dt><samp class="option">T</samp></dt> <dd> Time of the current frame, expressed in seconds. </dd> <dt><samp class="option">p(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the current plane. </dd> <dt><samp class="option">lum(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the luma plane. </dd> <dt><samp class="option">cb(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the blue-difference chroma plane. Return 0 if there is no such plane. </dd> <dt><samp class="option">cr(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the red-difference chroma plane. Return 0 if there is no such plane. </dd> <dt><samp class="option">r(x, y)</samp></dt> <dt><samp class="option">g(x, y)</samp></dt> <dt><samp class="option">b(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the red/green/blue component. Return 0 if there is no such component. </dd> <dt><samp class="option">alpha(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the alpha plane. Return 0 if there is no such plane. </dd> <dt><samp class="option">psum(x,y), lumsum(x, y), cbsum(x,y), crsum(x,y), rsum(x,y), gsum(x,y), bsum(x,y), alphasum(x,y)</samp></dt> <dd> Sum of sample values in the rectangle from (0,0) to (x,y), this allows obtaining sums of samples within a rectangle. See the functions without the sum postfix. </dd> <dt><samp class="option">interpolation</samp></dt> <dd> Set one of interpolation methods: <dl class="table"> <dt><samp class="option">nearest, n</samp></dt> <dt><samp class="option">bilinear, b</samp></dt> </dl> Default is bilinear. </dd> </dl>

For functions, if <var class="var">x</var> and <var class="var">y</var> are outside the area, the value will be automatically clipped to the closer edge. Please note that this filter can use multiple threads in which case each slice will have its own expression state. If you want to use only a single expression state because your expressions depend on previous state then you should limit the number of filter threads to 1. <h4 class="subsection">39.112.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Flip the image horizontally: <pre class="example-preformatted">geq=p(W-X\,Y) </pre>

Generate a bidimensional sine wave, with angle <code class="code">PI/3</code> and a wavelength of 100 pixels: <pre class="example-preformatted">geq=128 + 100*sin(2*(PI/100)*(cos(PI/3)*(X-50*T) + sin(PI/3)*Y)):128:128 </pre>

Generate a fancy enigmatic moving light: <pre class="example-preformatted">nullsrc=s=256x256,geq=random(1)/hypot(X-cos(N*0.07)*W/2-W/2\,Y-sin(N*0.09)*H/2-H/2)^2*1000000*sin(N*0.02):128:128 </pre>

Generate a quick emboss effect: <pre class="example-preformatted">format=gray,geq=lum_expr='(p(X,Y)+(256-p(X-4,Y-4)))/2' </pre>

Modify RGB components depending on pixel position: <pre class="example-preformatted">geq=r='X/W*r(X,Y)':g='(1-X/W)*g(X,Y)':b='(H-Y)/H*b(X,Y)' </pre>

Create a radial gradient that is the same size as the input (also see the vignette filter): <pre class="example-preformatted">geq=lum=255*gauss((X/W-0.5)*3)*gauss((Y/H-0.5)*3)/gauss(0)/gauss(0),format=gray </pre>

 <h3 class="section">39.113 gradfun# TOC</h3>

Fix the banding artifacts that are sometimes introduced into nearly flat regions by truncation to 8-bit color depth. Interpolate the gradients that should go where the bands are, and dither them. It is designed for playback only. Do not use it prior to lossy compression, because compression tends to lose the dither and bring back the bands. It accepts the following parameters: <dl class="table"> <dt><samp

class=”option”>strength</samp></dt> <dd> The maximum amount by which the filter will change any one pixel. This is also the threshold for detecting nearly flat regions. Acceptable values range from .51 to 64; the default value is 1.2. Out-of-range values will be clipped to the valid range. </dd> <dt><samp class=”option”>radius</samp></dt> <dd> The neighborhood to fit the gradient to. A larger radius makes for smoother gradients, but also prevents the filter from modifying the pixels near detailed regions. Acceptable values are 8-32; the default value is 16. Out-of-range values will be clipped to the valid range. </dd> </dl>

Alternatively, the options can be specified as a flat string: <var class=”var”>strength</var>[:<var class=”var”>radius</var>] <h4 class=”subsection”>39.113.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply the filter with a <code class=”code”>3.5</code> strength and radius of <code class=”code”>8</code>: <pre class=”example-preformatted”>gradfun=3.5:8 </pre>

Specify radius, omitting the strength (which will fall-back to the default value): <pre class=”example-preformatted”>gradfun=radius=8 </pre>

 <h3 class=”section”>39.114 graphmonitor# TOC</h3> Show various filtergraph stats. With this filter one can debug complete filtergraph. Especially issues with links filling with queued frames. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>size, s</samp></dt> <dd> Set video output size. Default is <var class=”var”>hd720</var>. </dd> <dt><samp class=”option”>opacity, o</samp></dt> <dd> Set video opacity. Default is <var class=”var”>0.9</var>.  <h3 class="section">39.118 haldclut# TOC</h3>

Apply a Hald CLUT to a video stream. First input

is the video stream to process, and second one is the Hald CLUT. The Hald CLUT input can be a simple picture or a complete video stream. The filter accepts the following options: <dl class="table"> <dt><samp class="option">clut</samp></dt> <dd> Set which CLUT video frames will be processed from second input stream, can be <var class="var">first</var> or <var class="var">all</var>. Default is <var class="var">all</var>. </dd> <dt><samp class="option">shortest</samp></dt> <dd> Force termination when the shortest input terminates. Default is <code class="code">0</code>. </dd> <dt><samp class="option">repeatlast</samp></dt> <dd> Continue applying the last CLUT after the end of the stream. A value of <code class="code">0</code> disable the filter after the last frame of the CLUT is reached. Default is <code class="code">1</code>. </dd> </dl>

<code class="code">haldclut</code> also has the same interpolation options as lut3d (both filters share the same internals). This filter also supports the framesync options. More information about the Hald CLUT can be found on Eskil Steenberg’s website (Hald CLUT author) at <a class="url" href="http://www.quelsolaar.com/technology/clut.html">http://www.quelsolaar.com/technology/clut.html<
  <h4 class="subsection">39.118.1 Commands# TOC</h4>

This filter supports the <code class="code">interp</code> option as commands. <h4 class="subsection">39.118.2 Workflow examples# TOC</h4>

 <h4 class="subsubsection">39.118.2.1 Hald CLUT video stream# TOC</h4>

Generate an identity Hald CLUT stream altered with various effects: <pre class="example-preformatted">ffmpeg -f lavfi -i haldclutsrc=8 -vf "hue=H=2*PI*t:s=sin(2*PI*t)+1, curves=cross_process" -t 10 -c:v ffv1 clut.nut </pre>

Note: make sure you use a lossless codec. Then use it with <code class="code">haldclut</code> to apply it on some random stream:

 <pre class="example-preformatted">ffmpeg -f lavfi -i mandelbrot -i clut.nut -filter_complex '[0][1] haldclut' -t 20 mandelclut.mkv </pre>

The Hald CLUT will be applied to the 10 first seconds (duration of <samp class="file">clut.nut</samp>), then the latest picture of that CLUT stream will be applied to the remaining frames of the <code class="code">mandelbrot</code> stream. <h4 class="subsubsection">39.118.2.2 Hald CLUT with preview# TOC</h4>

A Hald CLUT is supposed to be a squared image of <code class="code">Level*Level*Level</code> by <code class="code">Level*Level*Level</code> pixels. For a given Hald CLUT, FFmpeg will select the biggest possible square starting at the top left of the picture. The remaining padding pixels (bottom or right) will be ignored. This area can be used to add a preview of the Hald CLUT. Typically, the following generated Hald CLUT will be supported by the <code class="code">haldclut</code> filter: <pre class="example-preformatted">ffmpeg -f lavfi -i haldclutsrc=8 -vf " pad=iw+320 [padded_clut]; smptebars=s=320x256, split [a][b]; [padded_clut][a] overlay=W-320:h, curves=color_negative [main]; [main][b] overlay=W-320" -frames:v 1 clut.png </pre>

It contains the original and a preview of the effect of the CLUT: SMPTE color bars are displayed on the right-top, and below the same color bars processed by the color changes. Then, the effect of this Hald CLUT can be visualized with: <pre class="example-preformatted">ffplay input.mkv -vf "movie=clut.png, [in] haldclut" </pre>

 <h3 class="section">39.119 hflip# TOC</h3>

Flip the input video horizontally. For example, to horizontally flip the input video with <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -i in.avi -vf "hflip" out.avi </pre>

 <h3 class="section">39.120 histeq# TOC</h3> This filter applies a global color histogram equalization on a per-frame basis. It can be used to correct video that has a compressed range of pixel intensities. The

filter redistributes the pixel intensities to equalize their distribution across the intensity range. It may be viewed as an "automatically adjusting contrast filter". This filter is useful only for correcting degraded or poorly captured source video. The filter accepts the following options: <dl class="table"> <dt><samp class="option">strength</samp></dt> <dd> Determine the amount of equalization to be applied. As the strength is reduced, the distribution of pixel intensities more-and-more approaches that of the input frame. The value must be a float number in the range [0,1] and defaults to 0.200. </dd> <dt><samp class="option">intensity</samp></dt> <dd> Set the maximum intensity that can generated and scale the output values appropriately. The strength should be set as desired and then the intensity can be limited if needed to avoid washing-out. The value must be a float number in the range [0,1] and defaults to 0.210. </dd> <dt><samp class="option">antibanding</samp></dt> <dd> Set the antibanding level. If enabled the filter will randomly vary the luminance of output pixels by a small amount to avoid banding of the histogram. Possible values are <code class="code">none</code>, <code class="code">weak</code> or <code class="code">strong</code>. It defaults to <code class="code">none</code>. </dd> </dl>

 <h3 class="section">39.121 histogram# TOC</h3>

Compute and draw a color distribution histogram for the input video. The computed histogram is a representation of the color component distribution in an image. Standard histogram displays the color components distribution in an image. Displays color graph for each color component. Shows distribution of the Y, U, V, A or R, G, B components, depending on input format, in the current frame. Below each graph a color component scale meter is shown. The filter accepts the following options: <dl class="table"> <dt><samp class="option">level_height</samp></dt> <dd> Set height of level. Default value is <code class="code">200</code>. Allowed range is [50, 2048]. </dd> <dt><samp class="option">scale_height</samp></dt> <dd> Set height of color scale. Default value is <code class="code">12</code>. Allowed range is [0, 40]. </dd> <dt><samp class="option">display_mode</samp></dt> <dd> Set display mode. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">stack</samp>’</dt> <dd> Per color component graphs are placed below each other. </dd> <dt>‘<samp class="samp">parade</samp>’</dt> <dd> Per color component graphs are placed side by side. </dd> <dt>‘<samp class="samp">overlay</samp>’</dt> <dd> Presents information identical to that in the <code class="code">parade</code>, except that the graphs representing color components are superimposed directly over one another. </dd> </dl> Default

is <code class="code">stack</code>. </dd> <dt><samp class="option">levels_mode</samp></dt> <dd> Set mode. Can be either <code class="code">linear</code>, or <code class="code">logarithmic</code>. Default is <code class="code">linear</code>. </dd> <dt><samp class="option">components</samp></dt> <dd> Set what color components to display. Default is <code class="code">7</code>. </dd> <dt><samp class="option">fgopacity</samp></dt> <dd> Set foreground opacity. Default is <code class="code">0.7</code>. </dd> <dt><samp class="option">bgopacity</samp></dt> <dd> Set background opacity. Default is <code class="code">0.5</code>. </dd> <dt><samp class="option">colors_mode</samp></dt> <dd> Set colors mode. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">whiteonblack</samp>’</dt> <dt>‘<samp class="samp">blackonwhite</samp>’</dt> <dt>‘<samp class="samp">whiteongray</samp>’</dt> <dt>‘<samp class="samp">blackongray</samp>’</dt> <dt>‘<samp class="samp">coloronblack</samp>’</dt> <dt>‘<samp class="samp">coloronwhite</samp>’</dt> <dt>‘<samp class="samp">colorongray</samp>’</dt> <dt>‘<samp class="samp">blackoncolor</samp>’</dt> <dt>‘<samp class="samp">whiteoncolor</samp>’</dt> <dt>‘<samp class="samp">grayoncolor</samp>’</dt> </dl> Default is <code class="code">whiteonblack</code>. </dd> </dl>

 <h3 class="section">39.122 hqdn3d# TOC</h3>

This is a high precision/quality 3d denoise filter. It aims to reduce image noise, producing smooth images and making still images really still. It should enhance compressibility. It accepts the following optional parameters: <dl class="table"> <dt><samp class="option">luma_spatial</samp></dt> <dd> A non-negative floating point number which specifies spatial luma strength. It defaults to 4.0. </dd> <dt><samp class="option">chroma_spatial</samp></dt>

<dd> A non-negative floating point number which specifies spatial chroma strength. It defaults to 3.0*<var class="var">luma_spatial</var>/4.0. </dd> <dt><samp class="option">luma_tmp</samp></dt> <dd> A floating point number which specifies luma temporal strength. It defaults to 6.0*<var class="var">luma_spatial</var>/4.0. </dd> <dt><samp class="option">chroma_tmp</samp></dt> <dd> A floating point number which specifies chroma temporal strength. It defaults to <var class="var">luma_tmp</var>*<var class="var">chroma_spatial</var>/<var class="var">luma_spatial</var>. </dd> </dl>

 <h4 class="subsection">39.122.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class="section">39.123 hwdownload# TOC</h3>

Download hardware frames to system memory. The input must be in hardware frames, and the output a non-hardware format. Not all formats will be supported on the output - it may be necessary to insert an additional <samp class="option">format</samp> filter immediately following in the graph to get the output in a supported format. <h3 class="section">39.124 hwmap# TOC</h3>

Map hardware frames to system memory or to another device. This filter has several different modes of operation; which one is used depends on the input and output formats: <ul class="itemize mark-bullet"> Hardware frame input, normal frame output

Map the input frames to system memory and pass them to the output. If the original hardware frame is later required (for example, after overlaying something else on part of it), the <samp class="option">hwmap</samp> filter can be used again in the next mode to retrieve it. Normal frame input, hardware frame output

If the input is actually a software-mapped hardware frame, then unmap it - that is, return the original hardware frame. Otherwise, a device must be provided. Create new hardware surfaces on that device for the output, then map them back to the software format at the input and give those frames to the preceding filter. This will then act like

the <samp class="option">hwupload</samp> filter, but may be able to avoid an additional copy when the input is already in a compatible format. Hardware frame input and output

A device must be supplied for the output, either directly or with the <samp class="option">derive_device</samp> option. The input and output devices must be of different types and compatible - the exact meaning of this is system-dependent, but typically it means that they must refer to the same underlying hardware context (for example, refer to the same graphics card). If the input frames were originally created on the output device, then unmap to retrieve the original frames. Otherwise, map the frames to the output device - create new hardware frames on the output corresponding to the frames on the input.

The following additional parameters are accepted: <dl class="table"> <dt><samp class="option">mode</samp></dt> <dd> Set the frame mapping mode. Some combination of: <dl class="table"> <dt><var class="var">read</var></dt> <dd> The mapped frame should be readable. </dd> <dt><var class="var">write</var></dt> <dd> The mapped frame should be writeable. </dd> <dt><var class="var">overwrite</var></dt> <dd> The mapping will always overwrite the entire frame. This may improve performance in some cases, as the original contents of the frame need not be loaded. </dd> <dt><var class="var">direct</var></dt> <dd> The mapping must not involve any copying. Indirect mappings to copies of frames are created in some cases where either direct mapping is not possible or it would have unexpected properties. Setting this flag ensures that the mapping is direct and will fail if that is not possible. </dd> </dl> Defaults to <var class="var">read+write</var> if not specified. </dd> <dt><samp class="option">derive_device <var class="var">type</var></samp></dt> <dd> Rather than using the device supplied at initialisation, instead derive a new device of type <var class="var">type</var> from the device the input frames exist on. </dd> <dt><samp class="option">reverse</samp></dt> <dd> In a hardware to hardware mapping, map in reverse - create frames in the sink and map them back to the source. This may be necessary in some cases where a mapping in one direction is required but only the opposite direction is supported by the devices being used. This option is dangerous - it may break the preceding filter in undefined ways if there are any additional constraints on that filter’s output. Do not use it without fully understanding the implications of its use. </dd> </dl>

 <h3 class="section">39.125 hwupload# TOC</h3>

Upload system memory frames to hardware surfaces. The

device to upload to must be supplied when the filter is initialised. If using ffmpeg, select the appropriate device with the <samp class="option">-filter_hw_device</samp> option or with the <samp class="option">derive_device</samp> option. The input and output devices must be of different types and compatible - the exact meaning of this is system-dependent, but typically it means that they must refer to the same underlying hardware context (for example, refer to the same graphics card). The following additional parameters are accepted: <dl class="table"> <dt><samp class="option">derive_device <var class="var">type</var></samp></dt> <dd> Rather than using the device supplied at initialisation, instead derive a new device of type <var class="var">type</var> from the device the input frames exist on. </dd> </dl>

exact key color, while 1.0 matches everything. </dd> <dt><samp class=”option”>blend</samp></dt> <dd> Blend percentage. Allowed range is from 0 to 1. Default value is 0. 0.0 makes pixels either fully transparent, or not transparent at all. Higher values result in semi-transparent pixels, with a higher transparency the more similar the pixels color is to the key color. </dd> </dl>

 <h3 class=”section”>39.131 hue# TOC</h3>

Modify the hue and/or the saturation of the input. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>h</samp></dt> <dd> Specify the hue angle as a number of degrees. It accepts an expression, and defaults to "0". </dd> <dt><samp class=”option”>s</samp></dt> <dd> Specify the saturation in the [-10,10] range. It accepts an expression and defaults to "1". </dd> <dt><samp class=”option”>H</samp></dt> <dd> Specify the hue angle as a number of radians. It accepts an expression, and defaults to "0". </dd> <dt><samp class=”option”>b</samp></dt> <dd> Specify the brightness in the [-10,10] range. It accepts an expression and defaults to "0". </dd> </dl>

<samp class=”option”>h</samp> and <samp class=”option”>H</samp> are mutually exclusive, and can’t be specified at the same time. The <samp class=”option”>b</samp>, <samp class=”option”>h</samp>, <samp class=”option”>H</samp> and <samp class=”option”>s</samp> option values are expressions containing the following constants: <dl class=”table”> <dt><samp class=”option”>n</samp></dt> <dd> frame count of the input frame starting from 0 </dd> <dt><samp class=”option”>pts</samp></dt> <dd> presentation timestamp of the input frame expressed in time base units </dd> <dt><samp class=”option”>r</samp></dt> <dd> frame rate of the input video, NAN if the input frame rate is unknown </dd> <dt><samp class=”option”>t</samp></dt> <dd> timestamp expressed in seconds, NAN if the input timestamp is unknown </dd> <dt><samp class=”option”>tb</samp></dt> <dd> time base of the input video </dd> </dl>

 <h4 class=”subsection”>39.131.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Set the hue to 90 degrees and the saturation to 1.0: <pre class=”example-preformatted”>hue=h=90:s=1 </pre>

Same command but expressing the hue in radians: <pre class=”example-preformatted”>hue=H=PI/2:s=1 </pre>

Rotate hue and make the saturation swing between 0 and 2 over a period of 1 second: <pre class=”example-preformatted”>hue="H=2*PI*t: s=sin(2*PI*t)+1" </pre>

Apply a 3 seconds saturation fade-in effect starting at 0: <pre class=”example-preformatted”>hue="s=min(t/3\,1)" </pre>

The general fade-in expression can be written as: <pre class=”example-preformatted”>hue="s=min(0\, max((t-START)/DURATION\, 1))" </pre>

Apply a 3 seconds saturation fade-out effect starting at 5 seconds: <pre class=”example-preformatted”>hue="s=max(0\, min(1\, (8-t)/3))" </pre>

The general fade-out expression can be written as: <pre class=”example-preformatted”>hue="s=max(0\, min(1\, (START+DURATION-t)/DURATION))" </pre>

 <h4 class=”subsection”>39.131.2 Commands# TOC</h4>

This filter supports the following commands: <dl class=”table”> <dt><samp class=”option”>b</samp></dt> <dt><samp class=”option”>s</samp></dt> <dt><samp class=”option”>h</samp></dt> <dt><samp class=”option”>H</samp></dt> <dd> Modify the hue and/or the saturation and/or brightness of the input video. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h3 class=”section”>39.132 huesaturation# TOC</h3> Apply hue-saturation-intensity adjustments to input video stream. This filter operates in RGB colorspace. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>hue</samp></dt> <dd> Set the hue shift in degrees to apply. Default is 0. Allowed range is from -180 to 180. </dd> <dt><samp class=”option”>saturation</samp></dt> <dd> Set the saturation shift. Default is 0. Allowed range is from -1 to 1. </dd> <dt><samp class=”option”>intensity</samp></dt>

<dd> Set the intensity shift. Default is 0. Allowed range is from -1 to 1. </dd> <dt><samp class=”option”>colors</samp></dt> <dd> Set which primary and complementary colors are going to be adjusted. This options is set by providing one or multiple values. This can select multiple colors at once. By default all colors are selected. <dl class=”table”> <dt>‘<samp class=”samp”>r</samp>’</dt> <dd> Adjust reds. </dd> <dt>‘<samp class=”samp”>y</samp>’</dt> <dd> Adjust yellows. </dd> <dt>‘<samp class=”samp”>g</samp>’</dt> <dd> Adjust greens. </dd> <dt>‘<samp class=”samp”>c</samp>’</dt> <dd> Adjust cyans. </dd> <dt>‘<samp class=”samp”>b</samp>’</dt> <dd> Adjust blues. </dd> <dt>‘<samp class=”samp”>m</samp>’</dt> <dd> Adjust magentas. </dd> <dt>‘<samp class=”samp”>a</samp>’</dt> <dd> Adjust all colors. </dd> </dl>

</dd> <dt><samp class=”option”>strength</samp></dt> <dd> Set strength of filtering. Allowed range is from 0 to 100. Default value is 1. </dd> <dt><samp class=”option”>rw, gw, bw</samp></dt> <dd> Set weight for each RGB component. Allowed range is from 0 to 1. By default is set to 0.333, 0.334, 0.333. Those options are used in saturation and lightess processing. </dd> <dt><samp class=”option”>lightness</samp></dt> <dd> Set preserving lightness, by default is disabled. Adjusting hues can change lightness from original RGB triplet, with this option enabled lightness is kept at same value. </dd> </dl>

 <h3 class=”section”>39.133 hysteresis# TOC</h3>

Grow first stream into second stream by connecting components. This makes it possible to build more robust edge masks. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes will be processed as bitmap, unprocessed planes will be copied from first stream. By default value 0xf, all planes will be processed. </dd> <dt><samp class=”option”>threshold</samp></dt> <dd> Set threshold which is used in filtering. If pixel component value is higher than this value filter algorithm for connecting components is activated. By default value is 0. </dd> </dl>

The <code class=”code”>hysteresis</code> filter also supports the framesync options. <h3 class=”section”>39.134 iccdetect# TOC</h3>

Detect the colorspace from an embedded ICC profile (if present), and update the frame’s tags accordingly. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>force</samp></dt> <dd> If true, the frame’s existing colorspace tags will always be overridden by values detected from an ICC profile. Otherwise, they will only be assigned if they contain <code class=”code”>unknown</code>. Enabled by default. </dd> </dl>

 <h3 class=”section”>39.135 iccgen# TOC</h3>

Generate ICC profiles and attach them to frames. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>color_primaries</samp></dt> <dt><samp class=”option”>color_trc</samp></dt> <dd> Configure the colorspace that the ICC profile will be generated for. The default value of <code class=”code”>auto</code> infers the value from the input frame’s metadata, defaulting to BT.709/sRGB as appropriate. See the setparams filter for a list of possible values, but note that <code class=”code”>unknown</code> are not valid values for this filter. </dd> <dt><samp class=”option”>force</samp></dt> <dd> If true, an ICC profile will be generated even if it would overwrite an already existing ICC profile. Disabled by default. </dd> </dl>

 <h3 class=”section”>39.136 identity# TOC</h3>

Obtain the identity score between two input videos. This filter takes two input videos. Both input videos must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained per component, average, min and max identity score is printed through the logging system. The filter stores the calculated identity scores of each frame in frame metadata. This filter also supports the framesync options. In the below example the input file <samp class=”file”>main.mpg</samp> being processed is compared with the reference file <samp class=”file”>ref.mpg</samp>.   <pre class=”example-preformatted”>ffmpeg -i main.mpg -i ref.mpg -lavfi identity -f null - </pre>

 <h3 class=”section”>39.137 idet# TOC</h3>

Detect video interlacing type. This filter tries to detect if

the input frames are interlaced, progressive, top or bottom field first. It will also try to detect fields that are repeated between adjacent frames (a sign of telecine). Single frame detection considers only immediately adjacent frames when classifying each frame. Multiple frame detection incorporates the classification history of previous frames. The filter will log these metadata values: <dl class="table"> <dt><samp class="option">single.current_frame</samp></dt> <dd> Detected type of current frame using single-frame detection. One of: “tff” (top field first), “bff” (bottom field first), “progressive”, or “undetermined” </dd> <dt><samp class="option">single.tff</samp></dt> <dd> Cumulative number of frames detected as top field first using single-frame detection. </dd> <dt><samp class="option">multiple.tff</samp></dt> <dd> Cumulative number of frames detected as top field first using multiple-frame detection. </dd> <dt><samp class="option">single.bff</samp></dt> <dd> Cumulative number of frames detected as bottom field first using single-frame detection. </dd> <dt><samp class="option">multiple.current_frame</samp></dt> <dd> Detected type of current frame using multiple-frame detection. One of: “tff” (top field first), “bff” (bottom field first), “progressive”, or “undetermined” </dd> <dt><samp class="option">multiple.bff</samp></dt> <dd> Cumulative number of frames detected as bottom field first using multiple-frame detection. </dd> <dt><samp class="option">single.progressive</samp></dt> <dd> Cumulative number of frames detected as progressive using single-frame detection. </dd> <dt><samp class="option">multiple.progressive</samp></dt> <dd> Cumulative number of frames detected as progressive using multiple-frame detection. </dd> <dt><samp class="option">single.undetermined</samp></dt> <dd> Cumulative number of frames that could not be classified using single-frame detection. </dd> <dt><samp class="option">multiple.undetermined</samp></dt> <dd> Cumulative number of frames that could not be classified using multiple-frame detection. </dd> <dt><samp class="option">repeated.current_frame</samp></dt> <dd> Which field in the current frame is repeated from the last. One of “neither”, “top”, or “bottom”. </dd> <dt><samp class="option">repeated.neither</samp></dt> <dd> Cumulative number of frames with no repeated field. </dd> <dt><samp class="option">repeated.top</samp></dt> <dd> Cumulative number of frames with the top field repeated from the previous frame’s top field. </dd> <dt><samp class="option">repeated.bottom</samp></dt> <dd> Cumulative number of frames with the bottom field repeated from the previous frame’s bottom field. </dd> </dl>

The filter accepts the following options: <dl class="table"> <dt><samp class="option">intl_thres</samp></dt> <dd> Set interlacing threshold. </dd> <dt><samp class="option">prog_thres</samp></dt> <dd> Set progressive threshold. </dd> <dt><samp class="option">rep_thres</samp></dt> <dd> Threshold for repeated field detection. </dd> <dt><samp class="option">half_life</samp></dt> <dd> Number of frames after

which a given frame’s contribution to the statistics is halved (i.e., it contributes only 0.5 to its classification). The default of 0 means that all frames seen are given full weight of 1.0 forever. </dd> <dt><samp class="option">analyze_interlaced_flag</samp></dt> <dd> When this is not 0 then idet will use the specified number of frames to determine if the interlaced flag is accurate, it will not count undetermined frames. If the flag is found to be accurate it will be used without any further computations, if it is found to be inaccurate it will be cleared without any further computations. This allows inserting the idet filter as a low computational method to clean up the interlaced flag </dd> </dl>

 <h4 class="subsection">39.137.1 Examples# TOC</h4>

Inspect the field order of the first 360 frames in a video, in verbose detail: <pre class="example-preformatted">ffmpeg -i INPUT -filter:v idet,metadata=mode=print -frames:v 360 -an -f null - </pre> The idet filter will add analysis metadata to each frame, which will then be discarded. At the end, the filter will also print a final report with statistics. <h3 class="section">39.138 il# TOC</h3>

Deinterleave or interleave fields. This filter allows one to process interlaced images fields without deinterlacing them. Deinterleaving splits the input frame into 2 fields (so called half pictures). Odd lines are moved to the top half of the output image, even lines to the bottom half. You can process (filter) them independently and then re-interleave them. The filter accepts the following options: <dl class="table"> <dt><samp class="option">luma_mode, l</samp></dt> <dt><samp class="option">chroma_mode, c</samp></dt> <dt><samp class="option">alpha_mode, a</samp></dt> <dd> Available values for <var class="var">luma_mode</var>, <var class="var">chroma_mode</var> and <var class="var">alpha_mode</var> are: <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dd> Do nothing. </dd> <dt>‘<samp class="samp">deinterleave, d</samp>’</dt> <dd> Deinterleave fields, placing one above the other. </dd> <dt>‘<samp class="samp">interleave, i</samp>’</dt> <dd> Interleave fields. Reverse the effect of deinterleaving. </dd> </dl> Default value is <code class="code">none</code>. </dd> <dt><samp class="option">luma_swap, ls</samp></dt> <dt><samp class="option">chroma_swap, cs</samp></dt> <dt><samp class="option">alpha_swap, as</samp></dt> <dd> Swap luma/chroma/alpha fields. Exchange even & odd lines. Default value is

<code class="code">0</code>. </dd> </dl>

 <h4 class="subsection">39.138.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">39.139 inflate# TOC</h3>

Apply inflate effect to the video. This filter replaces the pixel by the local(3x3) average by taking into account only values higher than the pixel. It accepts the following options: <dl class="table"> <dt><samp class="option">threshold0</samp></dt> <dt><samp class="option">threshold1</samp></dt> <dt><samp class="option">threshold2</samp></dt> <dt><samp class="option">threshold3</samp></dt> <dd> Limit the maximum change for each plane, default is 65535. If 0, plane will remain unchanged. </dd> </dl>

 <h4 class="subsection">39.143.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">39.144 latticepal# TOC</h3>

Convert packed RGB/BGR input to PAL8 with a per-frame palette whose colors are placed on a face-centered cubic (FCC) lattice spanning the RGB cube. Each frame gets its own palette, built only from the lattice colors actually used by that frame. If a frame uses more than 256 lattice colors, they are reduced by iteratively dropping the color whose removal has the least impact (its pixel count times the squared distance to the nearest remaining color) and mapping its pixels to that nearest remaining color. The alpha channel, if present, is ignored unless the <samp class="option">alpha</samp> option is set. The filter accepts the following options: <dl class="table"> <dt><samp class="option">density</samp></dt>

<dd> Set the lattice density as the number of lattice steps spanning one color axis (0 to 255). Higher values give a finer lattice and thus more possible colors, making it more likely that the per-frame color reduction has to drop some of them. At a density of <code class=”code”>7</code> with 256 palette entries no reduction ever happens since the whole lattice then holds exactly 256 points. Allowed range is <code class=”code”>1</code> to <code class=”code”>255</code>. Default is <code class=”code”>20</code>. </dd> <dt><samp class=”option”>max_colors</samp></dt> <dd> Set the maximum number of palette entries to use. Frames using more lattice colors than this are reduced accordingly. Allowed range is <code class=”code”>2</code> to <code class=”code”>256</code>. Default is <code class=”code”>256</code>. </dd> <dt><samp class=”option”>alpha</samp></dt> <dd> Quantize the alpha channel too, placing the palette colors on a 4 dimensional D4 lattice over RGBA instead of the FCC lattice over RGB. Inputs without an alpha channel are treated as opaque. With this option the density is limited to <code class=”code”>64</code>. Default is <code class=”code”>0</code> (alpha is ignored and the palette is fully opaque). </dd> <dt><samp class=”option”>refine</samp></dt> <dd> Redistribute the error introduced by dropping colors, which is otherwise uncompensated and can show as discolored patches. Frames that needed no reduction are not changed by this option. <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> No refinement. </dd> <dt>‘<samp class=”samp”>full</samp>’</dt> <dd> Run a Floyd-Steinberg error diffusion pass over the whole frame against the final palette. Most accurate on average, but redithers everything, including regions whose colors survived. </dd> <dt>‘<samp class=”samp”>residual</samp>’</dt> <dd> Diffuse only the residual between each pixel’s first pass quantized color and its final palette color. Pixels of surviving colors that receive no residual are unchanged, keeping the character of the selected dither mode outside the reduced regions. </dd> <dt>‘<samp class=”samp”>batched</samp>’</dt> <dd> Interleave color removal and rediffusion: drop half of the excess colors, rediffuse the whole frame against the survivors, recount the colors from the actual assignments and repeat. Colors that the dithering can reproduce by mixing become free to drop while extreme colors keep their pixels and are protected; this gives the best quality at the cost of about log2 of the number of dropped colors rediffusion passes. </dd> </dl>

Default is <code class=”code”>none</code>. </dd> <dt><samp class=”option”>dither</samp></dt> <dd> Select the dithering mode. Available algorithms are: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> No dithering. </dd> <dt>‘<samp class=”samp”>bayer</samp>’</dt> <dd> Ordered 8x8 dithering using the classic swscale dither matrix

with its per-channel decorrelation, offsets spanning one lattice period. </dd> <dt>‘<samp class=”samp”>blue_noise</samp>’</dt> <dd> Void-and-cluster blue noise dithering using three 64x64 masks generated at initialization, one per color channel. </dd> <dt>‘<samp class=”samp”>floyd_steinberg</samp>’</dt> <dd> Floyd-Steinberg error diffusion. </dd> </dl>

Default is <code class=”code”>floyd_steinberg</code>. </dd> </dl>

 <h3 class=”section”>39.145 lenscorrection# TOC</h3>

Correct radial lens distortion This filter can be used to correct for radial distortion as can result from the use of wide angle lenses, and thereby re-rectify the image. To find the right parameters one can use tools available for example as part of opencv or simply trial-and-error. To use opencv use the calibration sample (under samples/cpp) from the opencv sources and extract the k1 and k2 coefficients from the resulting matrix. Note that effectively the same filter is available in the open-source tools Krita and Digikam from the KDE project. In contrast to the vignette filter, which can also be used to compensate lens errors, this filter corrects the distortion of the image, whereas vignette corrects the brightness distribution, so you may want to use both filters together in certain cases, though you will have to take care of ordering, i.e. whether vignetting should be applied before or after lens correction. <h4 class=”subsection”>39.145.1 Options# TOC</h4>

The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>cx</samp></dt> <dd> Relative x-coordinate of the focal point of the image, and thereby the center of the distortion. This value has a range [0,1] and is expressed as fractions of the image width. Default is 0.5. </dd> <dt><samp class=”option”>cy</samp></dt> <dd> Relative y-coordinate of the focal point of the image, and thereby the center of the distortion. This value has a range [0,1] and is expressed as fractions of the image height. Default is 0.5. </dd> <dt><samp class=”option”>k1</samp></dt> <dd> Coefficient of the quadratic correction term. This value has a range [-1,1]. 0 means no correction. Default is 0. </dd> <dt><samp class=”option”>k2</samp></dt> <dd> Coefficient of the double quadratic correction term. This value has a range [-1,1]. 0 means no correction. Default is 0. </dd> <dt><samp class=”option”>i</samp></dt> <dd> Set interpo-

lation type. Can be <code class=”code”>nearest</code> or <code class=”code”>bilinear</code>. Default is <code class=”code”>nearest</code>. </dd> <dt><samp class=”option”>fc</samp></dt> <dd> Specify the color of the unmapped pixels. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. Default color is <code class=”code”>black@0</code>. </dd> </dl>

The formula that generates the correction is: <var class=”var”>r_src</var> = <var class=”var”>r_tgt</var> * (1 + <var class=”var”>k1</var> * (<var class=”var”>r_tgt</var> / <var class=”var”>r_0</var>)^2 + <var class=”var”>k2</var> * (<var class=”var”>r_tgt</var> / <var class=”var”>r_0</var>)^4) where <var class=”var”>r_0</var> is halve of the image diagonal and <var class=”var”>r_src</var> and <var class=”var”>r_tgt</var> are the distances from the focal point in the source and target images, respectively. <h4 class=”subsection”>39.145.2 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class=”section”>39.146 lensfun# TOC</h3>

Apply lens correction via the lensfun library (<a class=”url” href=”http://lensfun.sourceforge.net/”>http:/

The <code class=”code”>lensfun</code> filter requires the camera make, camera model, and lens model

to apply the lens correction. The filter will load the lensfun database and

query it to find the corresponding camera and lens entries in the database. As

long as these entries can be found with the given options, the filter can

perform corrections on frames. Note that incomplete strings will result in the

filter choosing the best match with the given options, and the filter will

output the chosen camera and lens models (logged with level "info"). You must

provide the make, camera model, and lens model as they are required.

To obtain a list of available makes and models, leave out one or both of <code class=”code”>make</code> and

<code class=”code”>model</code> options. The filter will send the full list to the log with level <code class=”code”>INFO</code>.

The first column is the make and the second column is the model.

To obtain a list of available lenses, set any values for make and model and leave out the

<code class=”code”>lens_model</code> option. The filter will send the full list of lenses in the log with level

<code class=”code”>INFO</code>. The ffmpeg tool will exit after the list is printed.

The filter accepts the following options:

<dl class=”table”>

<dt><samp class=”option”>make</samp></dt>

<dd> The make of the camera (for example, "Canon"). This option is required.

</dd>

<dt><samp class=”option”>model</samp></dt>

<dd> The model of the camera (for example, "Canon EOS 100D"). This option is

required.

</dd>

<dt><samp class=”option”>lens_model</samp></dt>

<dd> The model of the lens (for example, "Canon EF-S 18-55mm f/3.5-5.6 IS STM"). This

option is required.

</dd>

<dt><samp class=”option”>db_path</samp></dt>

<dd> The full path to the lens database folder. If not set, the filter will attempt to

load the database from the install path when the library was built. Default is unset.

</dd>

<dt><samp class=”option”>mode</samp></dt>

<dd> The type of correction to apply. The following values are valid options:

<dl class=”table”>

<dt>‘<samp class=”samp”>vignetting</samp>’</dt>

<dd> Enables fixing lens vignetting.

</dd>

<dt>‘<samp class=”samp”>geometry</samp>’</dt>

<dd> Enables fixing lens geometry. This is the default.

</dd>

<dt>‘<samp class=”samp”>subpixel</samp>’</dt>

<dd> Enables fixing chromatic aberrations.

</dd>

<dt>‘<samp class=”samp”>vig_geo</samp>’</dt>

<dd> Enables fixing lens vignetting and lens geometry.

</dd>

<dt>‘<samp class=”samp”>vig_subpixel</samp>’</dt>

<dd> Enables fixing lens vignetting and chromatic aberrations.

</dd>

<dt>‘<samp class=”samp”>distortion</samp>’</dt>

<dd> Enables fixing both lens geometry and chromatic aberrations.

</dd>

<dt>‘<samp class=”samp”>all</samp>’</dt>

<dd> Enables all possible corrections.

</dd>

</dl>

</dd>

<dt><samp class=”option”>focal_length</samp></dt>

<dd> The focal length of the image/video (zoom; expected constant for video). For

example, a 18–55mm lens has focal length range of [18–55], so a value in that

range should be chosen when using that lens. Default 18.

</dd>

<dt><samp class=”option”>aperture</samp></dt>

<dd> The aperture of the image/video (expected constant for video). Note that

aperture is only used for vignetting correction. Default 3.5.

</dd>

<dt><samp class=”option”>focus_distance</samp></dt>

<dd> The focus distance of the image/video (expected constant for video). Note that

focus distance is only used for vignetting and only slightly affects the

vignetting correction process. If unknown, leave it at the default value (which

is 1000).

</dd>

<dt><samp class=”option”>scale</samp></dt>

<dd> The scale factor which is applied after transformation. After correction the

video is no longer necessarily rectangular. This parameter controls how much of

the resulting image is visible. The value 0 means that a value will be chosen

automatically such that there is little or no unmapped area in the output

image. 1.0 means that no additional scaling is done. Lower values may result

in more of the corrected image being visible, while higher values may avoid

unmapped areas in the output.

</dd>

<dt><samp class=”option”>target_geometry</samp></dt>

<dd> The target geometry of the output image/video. The following values are valid

options:

<dl class=”table”>

<dt>‘<samp class=”samp”>rectilinear (default)</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye</samp>’</dt>

<dt>‘<samp class=”samp”>panoramic</samp>’</dt>

<dt>‘<samp class=”samp”>equirectangular</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_orthographic</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_stereographic</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_equisolid</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_thoby</samp>’</dt>

</dl>

</dd>

<dt><samp class=”option”>reverse</samp></dt>

<dd> Apply the reverse of image correction (instead of correcting distortion, apply

it).

</dd>

<dt><samp class=”option”>interpolation</samp></dt>

<dd> The type of interpolation used when correcting distortion. The following values

are valid options:

<dl class=”table”>

<dt>‘<samp class=”samp”>nearest</samp>’</dt>

<dt>‘<samp class=”samp”>linear (default)</samp>’</dt>

<dt>‘<samp class=”samp”>lanczos</samp>’</dt>

</dl>

</dd>

</dl>

 <h4 class=”subsection”>39.146.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply lens correction with make "Canon", camera model "Canon EOS 100D", and lens model "Canon EF-S 18-55mm f/3.5-5.6 IS STM" with focal length of "18" and aperture of "8.0".

clockwise by the specified angle. <dl class="table"> <dt>‘<samp class="samp">0, 360</samp>’</dt> <dt>‘<samp class="samp">90</samp>’</dt> <dt>‘<samp class="samp">180</samp>’</dt> <dt>‘<samp class="samp">270</samp>’</dt> </dl>

</dd> <dt><samp class="option">fps</samp></dt> <dd> Set the output frame rate. This can be rational, e.g. <code class="code">60000/1001</code>. If set to the special string <code class="code">none</code> (the default), input timestamps will instead be passed through to the output unmodified. Otherwise, the input video frames will be interpolated as necessary to rescale the video to the specified target framerate, in a manner as determined by the <samp class="option">frame_mixer</samp> option. </dd> <dt><samp class="option">format</samp></dt> <dd> Set the output format override. If unset (the default), frames will be output in the same format as the respective input frames. Otherwise, format conversion will be performed. </dd> <dt><samp class="option">force_original_aspect_ratio</samp></dt> <dt><samp class="option">force_divisible_by</samp></dt> <dd> Work the same as the identical scale filter options. Note that <samp class="option">force_divisible_by</samp> also works with <code class="code">fit_sense=constraint</code>. </dd> <dt><samp class="option">reset_sar</samp></dt> <dd> If enabled, output frames will always have a pixel aspect ratio of 1:1. If disabled (the default), any aspect ratio mismatches, including those from e.g. anamorphic video sources, are forwarded to the output pixel aspect ratio. </dd> <dt><samp class="option">normalize_sar</samp></dt> <dd> Like <samp class="option">reset_sar</samp>, but instead of stretching the video content to fill the new output aspect ratio, the content is instead padded or cropped as necessary. Mutually exclusive with <samp class="option">fit_mode</samp>. Disabled by default. </dd> <dt><samp class="option">pad_crop_ratio</samp></dt> <dd> Specifies a ratio (between <code class="code">0.0</code> and <code class="code">1.0</code>) between padding and cropping when the input aspect ratio does not match the output aspect ratio and <samp class="option">normalize_sar</samp> is in effect. The default of <code class="code">0.0</code> always pads the content with black borders, while a value of <code class="code">1.0</code> always crops off parts of the content. Intermediate values are possible, leading to a mix of the two approaches. </dd> <dt><samp class="option">fit_mode</samp></dt> <dd> Specify the content fit strategy according to a list of predefined modes. Determines how the input image is to be placed inside the destination crop rectangle (as defined by <code class="code">pos_x/y</code> and <code class="code">pos_w/h</code>). The names and their implementations are taken from the CSS ’object-fit’ property. Note that this option is mutually exclusive with <samp class="option">normalize_sar</samp>. Defaults to <code

class=”code”>fill</code>. Valid values are: <dl class=”table”> <dt>‘<samp class=”samp”>fill</samp>’</dt> <dd> Stretch the input to the output rectangle, ignoring aspect ratio mismatches. Note that unless <samp class=”option”>reset_sar</samp> is also enabled, the output will still have the correct pixel aspect ratio tagged. </dd> <dt>‘<samp class=”samp”>contain</samp>’</dt> <dd> Scale the input to fit inside the output, preserving aspect ratio by padding. Equivalent to <samp class=”option”>normalize_sar</samp> with <samp class=”option”>pad_crop_ratio</samp> set to <code class=”code”>0.0</code>. </dd> <dt>‘<samp class=”samp”>cover</samp>’</dt> <dd> Scale the input to fill the output, preserving aspect ratio by cropping. Equivalent to <samp class=”option”>normalize_sar</samp> with <samp class=”option”>pad_crop_ratio</samp> set to <code class=”code”>1.0</code>. </dd> <dt>‘<samp class=”samp”>none, place</samp>’</dt> <dd> Don’t scale the input. The input will be placed inside the output rectangle at its natural size; which may result in additional padding or cropping. </dd> <dt>‘<samp class=”samp”>scale_down</samp>’</dt> <dd> Scale the input down as much as needed to fit inside the output. Equivalent to either <code class=”code”>contain</code> or <code class=”code”>none</code>, depending on whether the input is larger than the output or not. </dd> </dl>

</dd> <dt><samp class=”option”>fit_sense</samp></dt> <dd> When <samp class=”option”>fit_mode</samp> is in use, this option controls how the fit strategy is applied against the specified output resolution. Mutually exclusive with <samp class=”option”>force_original_aspect_ratio</samp>. Valid values are: <dl class=”table”> <dt>‘<samp class=”samp”>target</samp>’</dt> <dd> The computed output resolution is taken as the exact size of the output frame. This is the default behavior. </dd> <dt>‘<samp class=”samp”>constraint</samp>’</dt> <dd> The computed output resolution is a size reference against which the fit mode is applied, enlarging or decreasing the true frame size as needed to fit the content. </dd> </dl>

</dd> <dt><samp class=”option”>fillcolor</samp></dt> <dd> Set the color used to fill the output area not covered by the output image, for example as a result of <samp class=”option”>normalize_sar</samp>. For the general syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. Defaults to <code class=”code”>black@0</code>. </dd> <dt><samp class=”option”>corner_rounding</samp></dt> <dd> Render frames with rounded corners. The value, given as a float ranging from <code class=”code”>0.0</code> to <code class=”code”>1.0</code>, indicates the relative degree of rounding, from fully square to fully circular. In other words, it gives the radius divided by half the smaller side length. Defaults to <code class=”code”>0.0</code>. </dd>

<dt><samp class=”option”>lut</samp></dt> <dd> Specifies a custom LUT (in Adobe .cube format) to apply to the colors as part of color conversion. The exact interpretation depends on the value of <samp class=”option”>lut_type</samp>. </dd> <dt><samp class=”option”>lut_type</samp></dt> <dd> Controls the interpretation of color values fed to and from the LUT specified as <samp class=”option”>lut</samp>. Valid values are: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Chooses the interpretation of the LUT automatically from tagged metadata, and otherwise falls back to ‘<samp class=”samp”>native</samp>’. (Default) </dd> <dt>‘<samp class=”samp”>native</samp>’</dt> <dd> Applied to raw image contents in its native RGB colorspace (non-linear light), before conversion to the output color space. </dd> <dt>‘<samp class=”samp”>normalized</samp>’</dt> <dd> Applied to the normalized RGB image contents, in linear light, before conversion to the output color space. </dd> <dt>‘<samp class=”samp”>conversion</samp>’</dt> <dd> Fully replaces the conversion from the image color space to the output color space. If such a LUT is present, it has the highest priority, and overrides any ICC profiles, as well as options related to tone mapping and output colorimetry (<samp class=”option”>color_primaries</samp>, <samp class=”option”>color_trc</samp>). </dd> </dl>

</dd> <dt><samp class=”option”>extra_opts</samp></dt> <dd> Pass extra libplacebo internal configuration options. These can be specified as a list of <var class=”var”>key</var>=<var class=”var”>value</var> pairs separated by ’:’. The following example shows how to configure a custom filter kernel ("EWA LanczosSharp") and use it to double the input image resolution: <pre class=”example-preformatted”>-vf "libplacebo=w=iw*2:h=ih*2:extra_opts='upscaler=custom\:upscaler_preset=ewa_
</pre>

</dd> <dt><samp class=”option”>shader_cache</samp></dt> <dd> File path of a cache directory that libplacebo will use to store and load cached shader objects. This cache is not cleaned up automatically. If the path does not end in a directory separator, the generated filenames will be effectively prefixed by the last path component. All directories must already exist.   <pre class=”example-preformatted”>-vf "libplacebo=shader_cache=/tmp/pl-shader-" </pre>

</dd> <dt><samp class=”option”>inherit_device</samp></dt> <dd> Take the Vulkan device from the hardware frames arriving on the input, instead of creating a private one from the filter’s own hardware device. This is useful when the input frames originate on another API (for example CUDA frames uploaded to Vulkan by <code class=”code”>hwupload</code>) and the filter’s device is not itself a Vulkan device: libplacebo would otherwise spin up a separate Vulkan device

that the input frames do not belong to, and the frames could not be mapped. When enabled, the filter requires Vulkan hardware frames on the input and will fail negotiation otherwise. Disabled by default.   <pre class=”example-preformatted”>-init_hw_device vulkan=vk:0 -init_hw_device cuda@vk -filter_hw_device cuda0 ... -vf "hwupload=derive_device=vulkan,libplacebo=inherit_device=1" </pre>

</dd> <dt><samp class=”option”>colorspace</samp></dt> <dt><samp class=”option”>color_primaries</samp></dt> <dt><samp class=”option”>color_trc</samp></dt> <dt><samp class=”option”>range</samp></dt> <dt><samp class=”option”>chroma_location</samp><
<dd> Configure the colorspace that output frames will be delivered in. For any value other than the default <code class=”code”>auto</code>, conversion will be performed. With <code class=”code”>auto</code>, <samp class=”option”>color_primaries</samp> and <samp class=”option”>color_trc</samp> keep the values of the input frames, while <samp class=”option”>colorspace</samp>, <samp class=”option”>range</samp> and <samp class=”option”>chroma_location</samp> use the values negotiated with the filtergraph, which are those of the input unless a following filter requires others. See the setparams filter for a list of possible values. </dd> <dt><samp class=”option”>alpha_mode</samp></dt> <dd> Choose the desired output alpha mode, when the output format has an alpha channel. See the setparams filter for a list of possible values. </dd> <dt><samp class=”option”>apply_filmgrain</samp></dt> <dd> Apply film grain (e.g. AV1 or H.274) if present in source frames, and strip it from the output. Enabled by default. </dd> <dt><samp class=”option”>apply_dolbyvision</samp></dt> <dd> Apply Dolby Vision RPU metadata if present in source frames, and strip it from the output. Enabled by default. Note that Dolby Vision will always output BT.2020+PQ, overriding the usual input frame metadata. These will also be picked as the values of <code class=”code”>auto</code> for the respective frame output options. </dd> </dl>

In addition to the expression constants documented for the scale filter, the <samp class=”option”>crop_w</samp>, <samp class=”option”>crop_h</samp>, <samp class=”option”>crop_x</samp>, <samp class=”option”>crop_y</samp>, <samp class=”option”>pos_w</samp>, <samp class=”option”>pos_h</samp>, <samp class=”option”>pos_x</samp> and <samp class=”option”>pos_y</samp> options can also contain the following constants: <dl class=”table”> <dt><samp class=”option”>in_idx, idx</samp></dt> <dd> The (0-based) numeric index of the currently active input stream. </dd> <dt><samp class=”option”>crop_w, cw</samp></dt> <dt><samp class=”option”>crop_h, ch</samp></dt> <dd> The computed values of <samp class=”option”>crop_w</samp> and <samp class=”option”>crop_h</samp>. </dd> <dt><samp class=”option”>pos_w, pw</samp></dt> <dt><samp class=”option”>pos_h, ph</samp></dt> <dd> The computed values of <samp class=”option”>pos_w</samp>

and <samp class=”option”>pos_h</samp>. </dd> <dt><samp class=”option”>in_t, t</samp></dt> <dd> The input frame timestamp, in seconds. NAN if input timestamp is unknown. </dd> <dt><samp class=”option”>out_t, ot</samp></dt> <dd> The input frame timestamp, in seconds. NAN if input timestamp is unknown. </dd> <dt><samp class=”option”>n</samp></dt> <dd> The input frame number, starting with 0. </dd> </dl>

 <h4 class=”subsubsection”>39.148.1.2 Scaling# TOC</h4> The options in this section control how libplacebo performs upscaling and (if necessary) downscaling. Note that libplacebo will always internally operate on 4:4:4 content, so any sub-sampled chroma formats such as <code class=”code”>yuv420p</code> will necessarily be upsampled and downsampled as part of the rendering process. That means scaling might be in effect even if the source and destination resolution are the same. <dl class=”table”> <dt><samp class=”option”>upscaler</samp></dt> <dt><samp class=”option”>downscaler</samp></dt> <dd> Configure the filter kernel used for upscaling and downscaling. The respective defaults are <code class=”code”>spline36</code> and <code class=”code”>mitchell</code>. For a full list of possible values, pass <code class=”code”>help</code> to these options. The most important values are: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> Forces the use of built-in GPU texture sampling (typically bilinear). Extremely fast but poor quality, especially when downscaling. </dd> <dt>‘<samp class=”samp”>bilinear</samp>’</dt> <dd> Bilinear interpolation. Can generally be done for free on GPUs, except when doing so would lead to aliasing. Fast and low quality. </dd> <dt>‘<samp class=”samp”>nearest</samp>’</dt> <dd> Nearest-neighbour interpolation. Sharp but highly aliasing. </dd> <dt>‘<samp class=”samp”>oversample</samp>’</dt> <dd> Algorithm that looks visually similar to nearest-neighbour interpolation but tries to preserve pixel aspect ratio. Good for pixel art, since it results in minimal distortion of the artistic appearance. </dd> <dt>‘<samp class=”samp”>lanczos</samp>’</dt> <dd> Standard sinc-sinc interpolation kernel. </dd> <dt>‘<samp class=”samp”>spline36</samp>’</dt> <dd> Cubic spline approximation of lanczos. No difference in performance, but has very slightly less ringing. </dd> <dt>‘<samp class=”samp”>ewa_lanczos</samp>’</dt> <dd> Elliptically weighted average version of lanczos, based on a jinc-jinc kernel. This is also popularly referred to as just "Jinc scaling". Slow but very high quality. </dd> <dt>‘<samp class=”samp”>gaussian</samp>’</dt> <dd> Gaussian kernel. Has certain ideal mathematical properties, but subjectively very blurry. </dd> <dt>‘<samp

class=”samp”>mitchell</samp>’</dt> <dd> Cubic BC spline with parameters recommended by Mitchell and Netravali. Very little ringing. </dd> </dl>

</dd> <dt><samp class=”option”>frame_mixer</samp></dt> <dd> Controls the kernel used for mixing frames temporally. The default value is <code class=”code”>none</code>, which disables frame mixing. For a full list of possible values, pass <code class=”code”>help</code> to this option. The most important values are: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> Disables frame mixing, giving a result equivalent to "nearest neighbour" semantics. </dd> <dt>‘<samp class=”samp”>oversample</samp>’</dt> <dd> Oversamples the input video to create a "Smooth Motion"-type effect: if an output frame would exactly fall on the transition between two video frames, it is blended according to the relative overlap. This is the recommended option whenever preserving the original subjective appearance is desired. </dd> <dt>‘<samp class=”samp”>mitchell_clamp</samp>’</dt> <dd> Larger filter kernel that smoothly interpolates multiple frames in a manner designed to eliminate ringing and other artefacts as much as possible. This is the recommended option wherever maximum visual smoothness is desired. </dd> <dt>‘<samp class=”samp”>linear</samp>’</dt> <dd> Linear blend/fade between frames. Especially useful for constructing e.g. slideshows. </dd> </dl>

</dd> <dt><samp class=”option”>antiringing</samp></dt> <dd> Enables anti-ringing (for non-EWA filters). The value (between <code class=”code”>0.0</code> and <code class=”code”>1.0</code>) configures the strength of the anti-ringing algorithm. May increase aliasing if set too high. Disabled by default. </dd> <dt><samp class=”option”>sigmoid</samp></dt> <dd> Enable sigmoidal compression during upscaling. Reduces ringing slightly. Enabled by default. </dd> </dl>

 <h4 class=”subsubsection”>39.148.1.3 Deinterlacing# TOC</h4> Deinterlacing is automatically supported when frames are tagged as interlaced, however frames are not deinterlaced unless a deinterlacing algorithm is chosen. <dl class=”table”> <dt><samp class=”option”>deinterlace</samp></dt> <dd> The the deinterlacing algorithm to use. <dl class=”table”> <dt>‘<samp class=”samp”>weave</samp>’</dt> <dd> No deinterlacing, weave fields together into a single frame. This is the default. </dd> <dt>‘<samp class=”samp”>bob</samp>’</dt> <dd> Naive bob deinterlacing, simply repeat each field line twice. </dd> <dt>‘<samp class=”samp”>yadif</samp>’</dt>

<dd> Yet another deinterlacing filter. See the yadif filter for more details. </dd> <dt>‘<samp class="samp">bwdif</samp>’</dt> <dd> Bob weaver deinterlacing filter. See the bwdif filter for more details. </dd> </dl>

</dd> <dt><samp class="option">skip_spatial_check</samp></dt> <dd> Skip the spatial deinterlacing check when using <code class="code">yadif</code> deinterlacing. </dd> <dt><samp class="option">send_fields</samp></dt> <dd> Output a frame for each field, rather than for each frame. Note that this will always double the tagged output frame rate, even if the input does not contain any interlaced frames. Disabled by default. </dd> </dl>

 <h4 class="subsubsection">39.148.1.4 Debanding# TOC</h4> Libplacebo comes with a built-in debanding filter that is good at counteracting many common sources of banding and blocking. Turning this on is highly recommended whenever quality is desired. <dl class="table"> <dt><samp class="option">deband</samp></dt> <dd> Enable (fast) debanding algorithm. Disabled by default. </dd> <dt><samp class="option">deband_iterations</samp></dt> <dd> Number of deband iterations of the debanding algorithm. Each iteration is performed with progressively increased radius (and diminished threshold). Recommended values are in the range <code class="code">1</code> to <code class="code">4</code>. Defaults to <code class="code">1</code>. </dd> <dt><samp class="option">deband_threshold</samp></dt> <dd> Debanding filter strength. Higher numbers lead to more aggressive debanding. Defaults to <code class="code">4.0</code>. </dd> <dt><samp class="option">deband_radius</samp></dt> <dd> Debanding filter radius. A higher radius is better for slow gradients, while a lower radius is better for steep gradients. Defaults to <code class="code">16.0</code>. </dd> <dt><samp class="option">deband_grain</samp></dt> <dd> Amount of extra output grain to add. Helps hide imperfections. Defaults to <code class="code">6.0</code>. </dd> </dl>

 <h4 class="subsubsection">39.148.1.5 Color adjustment# TOC</h4> A collection of subjective color controls. Not very rigorous, so the exact effect will vary somewhat depending on the input primaries and colorspace. <dl class="table"> <dt><samp class="option">brightness</samp></dt> <dd> Brightness boost, between <code class="code">-1.0</code> and <code class="code">1.0</code>. Defaults to <code class="code">0.0</code>. </dd> <dt><samp class="option">contrast</samp></dt>

<dd> Contrast gain, between <code class="code">0.0</code> and <code class="code">16.0</code>. Defaults to <code class="code">1.0</code>. </dd> <dt><samp class="option">saturation</samp></dt> <dd> Saturation gain, between <code class="code">0.0</code> and <code class="code">16.0</code>. Defaults to <code class="code">1.0</code>. </dd> <dt><samp class="option">hue</samp></dt> <dd> Hue shift in radians, between <code class="code">-3.14</code> and <code class="code">3.14</code>. Defaults to <code class="code">0.0</code>. This will rotate the UV subvector, defaulting to BT.709 coefficients for RGB inputs. </dd> <dt><samp class="option">gamma</samp></dt> <dd> Gamma adjustment, between <code class="code">0.0</code> and <code class="code">16.0</code>. Defaults to <code class="code">1.0</code>. </dd> <dt><samp class="option">temperature</samp></dt> <dd> Color temperature adjustment. Lower values make the output warmer/redder, down to <code class="code">1667</code>, while higher values make the output cooler/bluer, up to <code class="code">25000</code>. Defaults to <code class="code">6500</code> (neutral white). </dd> <dt><samp class="option">cones</samp></dt> <dd> Cone model to use for color blindness simulation. Accepts any combination of <code class="code">l</code>, <code class="code">m</code> and <code class="code">s</code>. Here are some examples: <dl class="table"> <dt>‘<samp class="samp">m</samp>’</dt> <dd> Deuteranomaly / deuteranopia (affecting 3%-4% of the population) </dd> <dt>‘<samp class="samp">l</samp>’</dt> <dd> Protanomaly / protanopia (affecting 1%-2% of the population) </dd> <dt>‘<samp class="samp">l+m</samp>’</dt> <dd> Monochromacy (very rare) </dd> <dt>‘<samp class="samp">l+m+s</samp>’</dt> <dd> Achromatopsy (complete loss of daytime vision, extremely rare) </dd> </dl>

</dd> <dt><samp class="option">cone-strength</samp></dt> <dd> Gain factor for the cones specified by <code class="code">cones</code>, between <code class="code">0.0</code> and <code class="code">10.0</code>. A value of <code class="code">1.0</code> results in no change to color vision. A value of <code class="code">0.0</code> (the default) simulates complete loss of those cones. Values above <code class="code">1.0</code> result in exaggerating the differences between cones, which may help compensate for reduced color vision. </dd> </dl>

 <h4 class="subsubsection">39.148.1.6 Peak detection# TOC</h4> To help deal with sources that only have static HDR10 metadata (or no tagging whatsoever), libplacebo uses its own internal frame analysis compute shader to analyze source frames and adapt the tone mapping function in realtime. If this is too slow, or if exactly reproducible frame-perfect results

are needed, it’s recommended to turn this feature off. <dl class="table"> <dt><samp class="option">peak_detect</samp></dt> <dd> Enable HDR peak detection. Ignores static MaxCLL/MaxFALL values in favor of dynamic detection from the input. Note that the detected values do not get written back to the output frames, they merely guide the internal tone mapping process. Enabled by default. </dd> <dt><samp class="option">smoothing_period</samp></dt> <dd> Peak detection smoothing period, between <code class="code">0.0</code> and <code class="code">1000.0</code>. Higher values result in peak detection becoming less responsive to changes in the input. Defaults to <code class="code">20.0</code>. </dd> <dt><samp class="option">scene_threshold_low</samp></dt> <dt><samp class="option">scene_threshold_high</
<dd> Lower and upper thresholds for scene change detection. Expressed in a logarithmic scale between <code class="code">0.0</code> and <code class="code">100.0</code>. Default to <code class="code">1.0</code> and <code class="code">3.0</code>, respectively. Setting either to a negative value disables this functionality. </dd> <dt><samp class="option">percentile</samp></dt> <dd> Which percentile of the frame brightness histogram to use as the source peak for tone-mapping. Defaults to <code class="code">99.995</code>, a fairly conservative value. Setting this to <code class="code">100.0</code> disables frame histogram measurement and instead uses the true peak brightness for tone-mapping. </dd> </dl>

 <h4 class="subsubsection">39.148.1.7 Tone mapping# TOC</h4>
The options in this section control how libplacebo performs tone-mapping and gamut-mapping when dealing with mismatches between wide-gamut or HDR content. In general, libplacebo relies on accurate source tagging and mastering display gamut information to produce the best results. <dl class="table"> <dt><samp class="option">gamut_mode</samp></dt> <dd> How to handle out-of-gamut colors that can occur as a result of colorimetric gamut mapping. <dl class="table"> <dt>‘<samp class="samp">clip</samp>’</dt> <dd> Do nothing, simply clip out-of-range colors to the RGB volume. Low quality but extremely fast. </dd> <dt>‘<samp class="samp">perceptual</samp>’</dt>
<dd> Perceptually soft-clip colors to the gamut volume. This is the default. </dd> <dt>‘<samp class="samp">relative</samp>’</dt>
<dd> Relative colorimetric hard-clip. Similar to <code class="code">perceptual</code> but without the soft knee. </dd> <dt>‘<samp class="samp">saturation</samp>’</dt>
<dd> Saturation mapping, maps primaries directly to primaries in RGB space. Not recommended except for artificial computer graphics for which a bright, saturated display is desired. </dd> <dt>‘<samp class="samp">absolute</samp>’</dt> <dd> Absolute colori-

metric hard-clip. Performs no adjustment of the white point. </dd> <dt>‘<samp class=”samp”>desaturate</samp>’</dt> <dd> Hard-desaturates out-of-gamut colors towards white, while preserving the luminance. Has a tendency to distort the visual appearance of bright objects. </dd> <dt>‘<samp class=”samp”>darken</samp>’</dt> <dd> Linearly reduces content brightness to preserves saturated details, followed by clipping the remaining out-of-gamut colors. </dd> <dt>‘<samp class=”samp”>warn</samp>’</dt> <dd> Highlight out-of-gamut pixels (by inverting/marking them). </dd> <dt>‘<samp class=”samp”>linear</samp>’</dt> <dd> Linearly reduces chromaticity of the entire image to make it fit within the target color volume. Be careful when using this on BT.2020 sources without proper mastering metadata, as doing so will lead to excessive desaturation. </dd> </dl>

</dd> <dt><samp class=”option”>tonemapping</samp></dt> <dd> Tonemapping algorithm to use. Available values are: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Automatic selection based on internal heuristics. This is the default. </dd> <dt>‘<samp class=”samp”>clip</samp>’</dt> <dd> Performs no tone-mapping, just clips out-of-range colors. Retains perfect color accuracy for in-range colors but completely destroys out-of-range information. Does not perform any black point adaptation. Not configurable. </dd> <dt>‘<samp class=”samp”>st2094-40</samp>’</dt> <dd> EETF from SMPTE ST 2094-40 Annex B, which applies the Bezier curves from HDR10+ dynamic metadata based on Bezier curves to perform tone-mapping. The OOTF used is adjusted based on the ratio between the targeted and actual display peak luminances. </dd> <dt>‘<samp class=”samp”>st2094-10</samp>’</dt> <dd> EETF from SMPTE ST 2094-10 Annex B.2, which takes into account the input signal average luminance in addition to the maximum/minimum. The configurable contrast parameter influences the slope of the linear output segment, defaulting to <code class=”code”>1.0</code> for no increase/decrease in contrast. Note that this does not currently include the subjective gain/offset/gamma controls defined in Annex B.3. </dd> <dt>‘<samp class=”samp”>bt.2390</samp>’</dt> <dd> EETF from the ITU-R Report BT.2390, a hermite spline roll-off with linear segment. The knee point offset is configurable. Note that this parameter defaults to <code class=”code”>1.0</code>, rather than the value of <code class=”code”>0.5</code> from the ITU-R spec. </dd> <dt>‘<samp class=”samp”>bt.2446a</samp>’</dt> <dd> EETF from ITU-R Report BT.2446, method A. Designed for well-mastered HDR sources. Can be used for both forward and inverse tone mapping. Not configurable. </dd> <dt>‘<samp class=”samp”>spline</samp>’</dt> <dd> Simple spline consisting of two polynomials, joined by a single pivot point. The parameter gives the pivot point (in PQ space), defaulting to <code class=”code”>0.30</code>. Can be used for both

forward and inverse tone mapping. </dd> <dt>‘<samp class=”samp”>reinhard</samp>’</dt> <dd> Simple non-linear, global tone mapping algorithm. The parameter specifies the local contrast coefficient at the display peak. Essentially, a parameter of <code class=”code”>0.5</code> implies that the reference white will be about half as bright as when clipping. Defaults to <code class=”code”>0.5</code>, which results in the simplest formulation of this function. </dd> <dt>‘<samp class=”samp”>mobius</samp>’</dt> <dd> Generalization of the reinhard tone mapping algorithm to support an additional linear slope near black. The tone mapping parameter indicates the trade-off between the linear section and the non-linear section. Essentially, for a given parameter <var class=”var”>x</var>, every color value below <var class=”var”>x</var> will be mapped linearly, while higher values get non-linearly tone-mapped. Values near <code class=”code”>1.0</code> make this curve behave like <code class=”code”>clip</code>, while values near <code class=”code”>0.0</code> make this curve behave like <code class=”code”>reinhard</code>. The default value is <code class=”code”>0.3</code>, which provides a good balance between colorimetric accuracy and preserving out-of-gamut details. </dd> <dt>‘<samp class=”samp”>hable</samp>’</dt> <dd> Piecewise, filmic tone-mapping algorithm developed by John Hable for use in Uncharted 2, inspired by a similar tone-mapping algorithm used by Kodak. Popularized by its use in video games with HDR rendering. Preserves both dark and bright details very well, but comes with the drawback of changing the average brightness quite significantly. This is sort of similar to <code class=”code”>reinhard</code> with parameter <code class=”code”>0.24</code>. </dd> <dt>‘<samp class=”samp”>gamma</samp>’</dt> <dd> Fits a gamma (power) function to transfer between the source and target color spaces, effectively resulting in a perceptual hard-knee joining two roughly linear sections. This preserves details at all scales fairly accurately, but can result in an image with a muted or dull appearance. The parameter is used as the cutoff point, defaulting to <code class=”code”>0.5</code>. </dd> <dt>‘<samp class=”samp”>linear</samp>’</dt> <dd> Linearly stretches the input range to the output range, in PQ space. This will preserve all details accurately, but results in a significantly different average brightness. Can be used for inverse tone-mapping in addition to regular tone-mapping. The parameter can be used as an additional linear gain coefficient (defaulting to <code class=”code”>1.0</code>). </dd> </dl>

</dd> <dt><samp class=”option”>tonemapping_param</samp></dt> <dd> For tunable tone mapping functions, this parameter can be used to fine-tune the curve behavior. Refer to the documentation of <code class=”code”>tonemapping</code>. The default value of <code class=”code”>0.0</code> is replaced by the curve’s preferred default setting. </dd> <dt><samp class=”option”>inverse_tonemapping</samp></dt>

<dd> If enabled, this filter will also attempt stretching SDR signals to fill HDR output color volumes. Disabled by default. </dd> <dt><samp class=”option”>tonemapping_lut_size</samp></dt> <dd> Size of the tone-mapping LUT, between <code class=”code”>2</code> and <code class=”code”>1024</code>. Defaults to <code class=”code”>256</code>. Note that this figure is squared when combined with <code class=”code”>peak_detect</code>. </dd> <dt><samp class=”option”>contrast_recovery</samp></dt> <dd> Contrast recovery strength. If set to a value above <code class=”code”>0.0</code>, the source image will be divided into high-frequency and low-frequency components, and a portion of the high-frequency image is added back onto the tone-mapped output. May cause excessive ringing artifacts for some HDR sources, but can improve the subjective sharpness and detail left over in the image after tone-mapping. Defaults to <code class=”code”>0.30</code>. </dd> <dt><samp class=”option”>contrast_smoothness</samp></dt> <dd> Contrast recovery lowpass kernel size. Defaults to <code class=”code”>3.5</code>. Increasing or decreasing this will affect the visual appearance substantially. Has no effect when <code class=”code”>contrast_recovery</code> is disabled. </dd> </dl>

 <h4 class=”subsubsection”>39.148.1.8 Dithering# TOC</h4> By default, libplacebo will dither whenever necessary, which includes rendering to any integer format below 16-bit precision. It’s recommended to always leave this on, since not doing so may result in visible banding in the output, even if the <code class=”code”>debanding</code> filter is enabled. If maximum performance is needed, use <code class=”code”>ordered_fixed</code> instead of disabling dithering. <dl class=”table”> <dt><samp class=”option”>dithering</samp></dt> <dd> Dithering method to use. Accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> Disables dithering completely. May result in visible banding. </dd> <dt>‘<samp class=”samp”>blue</samp>’</dt> <dd> Dither with pseudo-blue noise. This is the default. </dd> <dt>‘<samp class=”samp”>ordered</samp>’</dt> <dd> Tunable ordered dither pattern. </dd> <dt>‘<samp class=”samp”>ordered_fixed</samp>’</dt> <dd> Faster ordered dither with a fixed size of <code class=”code”>6</code>. Texture-less. </dd> <dt>‘<samp class=”samp”>white</samp>’</dt> <dd> Dither with white noise. Texture-less. </dd> </dl>

</dd> <dt><samp class=”option”>dither_lut_size</samp></dt> <dd> Dither LUT size, as log base2 between <code class=”code”>1</code> and <code class=”code”>8</code>. Defaults to <code class=”code”>6</code>, corresponding to a LUT size of <code class=”code”>64x64</code>. </dd> <dt><samp class=”option”>dither_temporal</samp></dt>

<dd> Enables temporal dithering. Disabled by default. </dd>
</dl>

 <h4 class="subsubsection">39.148.1.9 Custom shaders# TOC</h4>
libplacebo supports a number of custom shaders based on the mpv .hook GLSL syntax. A collection of such shaders can be found here: https://github.com/mpv-player/mpv/wiki/User-Scripts#user-shaders A full description of the mpv shader format is beyond the scope of this section, but a summary can be found here: https://mpv.io/manual/master/#options-glsl-shader <dl class="table"> <dt><samp class="option">custom_shader_path</samp></dt>
<dd> Specifies a path to a custom shader file to load at runtime. </dd> <dt><samp class="option">custom_shader_bin</samp></dt>
<dd> Specifies a complete custom shader as a raw string. </dd>
</dl>

 <h4 class="subsubsection">39.148.1.10 Debugging / performance# TOC</h4> All of the options in this section default off. They may be of assistance when attempting to squeeze the maximum performance at the cost of quality. <dl class="table"> <dt><samp class="option">skip_aa</samp></dt>
<dd> Disable anti-aliasing when downscaling. </dd> <dt><samp class="option">disable_linear</samp></dt> <dd> Disable linear light scaling. </dd> <dt><samp class="option">disable_builtin</samp></dt>
<dd> Disable built-in GPU sampling (forces LUT). </dd>

 <h4 class="subsection">39.173.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">39.174 morpho# TOC</h3>

This filter allows to apply main morphological grayscale transforms, erode and dilate with arbitrary structures set in second input stream. Unlike naive implementation and much slower performance in erosion and dilation filters, when speed is critical <code class="code">morpho</code> filter should be used instead. A description of accepted options follows, <dl class="table"> <dt><samp class="option">mode</samp></dt> <dd> Set morphological transform to apply, can be: <dl class="table"> <dt>‘<samp class="samp">erode</samp>’</dt> <dt>‘<samp class="samp">dilate</samp>’</d <dt>‘<samp class="samp">open</samp>’</dt> <dt>‘<samp class="samp">close</samp>’</dt> <dt>‘<samp class="samp">gradient</samp>’< <dt>‘<samp class="samp">tophat</samp>’</dt> <dt>‘<samp class="samp">blackhat</samp>’</dt> </dl> Default is <code class="code">erode</code>. </dd> <dt><samp class="option">planes</samp></dt> <dd> Set planes to filter, by default all planes except alpha are filtered. </dd> <dt><samp class="option">structure</samp></dt> <dd> Set which structure video frames will be processed from second input stream, can be <var class="var">first</var> or <var class="var">all</var>. Default is <var class="var">all</var>. </dd> </dl>

The <code class="code">morpho</code> filter also supports the

framesync options. <h4 class=”subsection”>39.174.1 Commands# TOC</h4>

This filter supports same commands as options. <h3 class=”section”>39.175 mpdecimate# TOC</h3>

Drop frames that do not differ greatly from the previous frame in order to reduce frame rate. The main use of this filter is for very-low-bitrate encoding (e.g. streaming over dialup modem), but it could in theory be used for fixing movies that were inverse-telecined incorrectly. A description of the accepted options follows. <dl class=”table”> <dt><samp class=”option”>mode</samp></dt> <dd> Set the mode. If the value is 0, the filter drops similar frames. If the value is 1, the filter keeps only frames that are one representative of sufficiently long duplicate runs. Default value is 0. </dd> <dt><samp class=”option”>max</samp></dt> <dd> For mode 0: Set the maximum number of consecutive frames which can be dropped (if positive), or the minimum interval between dropped frames (if negative). If the value is 0, the frame is dropped disregarding the number of previous sequentially dropped frames. Default value is 0. </dd> <dt><samp class=”option”>min</samp></dt> <dd> For mode 1: Set the minimum number of frame duplicates to mark the frame as non-unique and keep the first occurrence of it. Default value is 1. </dd> <dt><samp class=”option”>keep</samp></dt> <dd> For mode 0: Set the maximum number of consecutive similar frames to ignore before to start dropping them. If the value is 0, the frame is dropped disregarding the number of previous sequentially similar frames. Default value is 0. </dd> <dt><samp class=”option”>hi</samp></dt> <dt><samp class=”option”>lo</samp></dt> <dt><samp class=”option”>frac</samp></dt> <dd> Set the dropping threshold values. Values for <samp class=”option”>hi</samp> and <samp class=”option”>lo</samp> are for 8x8 pixel blocks and represent actual pixel value differences, so a threshold of 64 corresponds to 1 unit of difference for each pixel, or the same spread out differently over the block. A frame is a candidate for dropping if no 8x8 blocks differ by more than a threshold of <samp class=”option”>hi</samp>, and if no more than <samp class=”option”>frac</samp> blocks (1 meaning the whole image) differ by more than a threshold of <samp class=”option”>lo</samp>. Default value for <samp class=”option”>hi</samp> is 64*12, default value for <samp class=”option”>lo</samp> is 64*5, and default value for <samp class=”option”>frac</samp> is 0.33. </dd> </dl>

 <h3 class="section">39.176 msad# TOC</h3>

Obtain the MSAD (Mean Sum of Absolute Differences) between two input videos. This filter takes two input videos. Both input videos must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained per component, average, min and max MSAD is printed through the logging system. The filter stores the calculated MSAD of each frame in frame metadata. This filter also supports the framesync options. In the below example the input file <samp class="file">main.mpg</samp> being processed is compared with the reference file <samp class="file">ref.mpg</samp>.   <pre class="example-preformatted">ffmpeg -i main.mpg -i ref.mpg -lavfi msad -f null - </pre>

 <h3 class="section">39.177 multiply# TOC</h3> Multiply first video stream pixels values with second video stream pixels values. The filter accepts the following options: <dl class="table"> <dt><samp class="option">scale</samp></dt> <dd> Set the scale applied to second video stream. By default is <code class="code">1</code>. Allowed range is from <code class="code">0</code> to <code class="code">9</code>. </dd> <dt><samp class="option">offset</samp></dt> <dd> Set the offset applied to second video stream. By default is <code class="code">0.5</code>. Add temporal and uniform noise to input video: <pre class="example-preformatted">noise=alls=20:allf=t+u </pre>

 <h3 class="section">39.183 normalize# TOC</h3>

Normalize RGB video (aka histogram stretching, contrast stretching).

See: https://en.wikipedia.org/wiki/Normalization_(image_processing) For each channel of each frame, the filter computes the input range and maps it linearly to the user-specified output range. The output range defaults to the full dynamic range from pure black to pure white. Temporal smoothing can be used on the input range to reduce flickering (rapid changes in brightness) caused when small dark or bright objects enter or leave the scene. This is similar to the auto-exposure (automatic gain control) on a video camera, and, like a video camera, it may cause a period of over- or under-exposure of the video. The R,G,B channels can be normalized independently, which may cause some color shifting, or linked together as a single channel, which prevents color shifting. Linked normalization preserves hue. Independent normalization does not, so it can be used to remove some color casts. Independent and linked normalization can be combined in any ratio. The normalize filter accepts the following options: <dl class="table"> <dt><samp class="option">blackpt</samp></dt> <dt><samp class="option">whitept</samp></dt> <dd> Colors which define the output range. The minimum input value is mapped to the <var class="var">blackpt</var>. The maximum input value is mapped to the <var class="var">whitept</var>. The defaults are black and white respectively. Specifying white for <var class="var">blackpt</var> and black for <var class="var">whitept</var> will give color-inverted, normalized video. Shades of grey can be used to reduce the dynamic range (contrast). Specifying saturated colors here can create some interesting effects. </dd> <dt><samp class="option">smoothing</samp></dt> <dd> The number of previous frames to use for temporal smoothing. The input range of each channel is smoothed using a rolling average over the current frame and the <var class="var">smoothing</var> previous frames. The default is 0 (no temporal smoothing). </dd> <dt><samp class="option">independence</samp></dt> <dd> Controls the ratio of independent (color shifting) channel normalization to linked (color preserving) normalization. 0.0 is fully linked, 1.0 is fully independent. Defaults to 1.0 (fully independent). </dd> <dt><samp class="option">strength</samp></dt> <dd> Overall strength of the filter. 1.0 is full strength. 0.0 is a rather expensive no-op. Defaults to 1.0 (full strength). </dd> </dl>

 <h4 class="subsection">39.183.1 Commands# TOC</h4> This filter supports same commands as options, excluding <var class="var">smoothing</var> option. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h4 class="subsection">39.183.2 Examples<a class="anchor hidden-xs" href="#Examples-

TOC</h3>

Pass the video source unchanged to the output.
<h3 class="section">39.185 ocio# TOC</h3>
OpenColorIO library filter This filter allows you to do color management using the OpenColorIO library. See https://opencolorio.org/ for more details. To Enable compilation of this filter, you need to configure FFmpeg with <code class="code">--enable-libopencolorio</code>.
It accepts the following options: <dl class="table"> <dt><samp class="option">config</samp></dt> <dd> By default the filter will use the OCIO config defined by the OCIO environment variable, but this parameter allows you to explicitly specify its location. If you are getting started, you can use config=ocio://studio-config-v1.0.0_aces-v1.3_ocio-v2.1 which specifies one of the built in defaults. </dd> <dt><samp class="option">input</samp></dt> <dd> Set the input colorspace. </dd> <dt><samp class="option">output</samp></dt> <dd> Set the output colorspace. </dd> <dt><samp class="option">display</samp></dt>
<dd> Set the display colorspace, used in combination with view. </dd> <dt><samp class="option">view</samp></dt> <dd> Set the view colorspace, used in combination with display. </dd> <dt><samp

class=”option”>inverse</samp></dt> <dd> When used in combination with display and view, this inverts the transform, so going from a display/view to the "input colorspace". </dd> <dt><samp class=”option”>filetransform</samp></dt> <dd> Allows you to specify an external file-transform to use instead of the OCIO config file. This is useful for applying a single transform without needing a full OCIO config file. </dd> <dt><samp class=”option”>format</samp></dt> <dd> Allow you to specify the output pix_fmt of the OCIO filter. This *has* to be a RGB colorspace, so you are limited to rgb24, rgba, rgb48, rgba64, gbrp10, gbrap10, gbrp12, gbrap12, gbrpf32 and gbrapf32; for most encoding we would recommend rgb48. Half-float (gbrpf16, gbrapf16) is accepted as input but is not a valid output format, because swscale has no half-float write support and its legacy half-float read path clamps values to [0,1]. When this option is not set, the output format defaults to the input format, except that half-float input is promoted to the matching float format. Where negotiation cannot yet tell whether the input will be half-float, the output falls back to float, so a float output may be selected even when the input turns out to be an integer format. </dd> <dt><samp class=”option”>context_params</samp></dt> <dd> Allow you to specify additional context parameters for the OCIO filter. This is a list of key=value pairs, separated by colons. </dd> </dl>

 <h4 class=”subsection”>39.185.1 Examples# TOC</h4>

Map from ACEScg to ACEScct, this assumes the OCIO file is defined with the OCIO environment variable. <pre class=”example-preformatted”>input=ACEScg:output=ACEScct:format=rgb48 </pre>

Map from ACEScg to a sRGB display using the "ACES 1.0 - SDR Video" view transform, this assumes the OCIO file is defined with the OCIO environment variable. Note you will need to wrap the argument in quotes to ensure that the spaces are interpreted correctly. <pre class=”example-preformatted”>input=ACEScg:display=sRGB - Display:view=ACES 1.0 - SDR Video:format=rgb48 </pre>

As above but using the OCIO file studio-config-v1.0.0_aces-v1.3_ocio-v2.1_ns.ocio rather than the OCIO environment variable. <pre class=”example-preformatted”>config=studio-config-v1.0.0_aces-v1.3_ocio-v2.1_ns.ocio:input=ACEScg:display=sRGB - Display:view=ACES 1.0 - SDR Video:format=rgb48 </pre>

If you are converting to YCrCb you still will want to set the color matrix for the conversion. This is a good example of combining the two. <div

class=”example”> <pre class=”example-preformatted”>ffmpeg -y -i SOURCE-FRAMES.%05d.exr -c:v libx265 -vf "ocio=input=ACEScg:output=ACEScct:format=rgb48,scale=in_col OUTPUTFILE.mov </pre>

 <h3 class=”section”>39.186 ocr# TOC</h3> Optical Character Recognition This filter uses Tesseract for optical character recognition. To enable compilation of this filter, you need to configure FFmpeg with <code class=”code”>--enable-libtesseract</code>. It accepts the following options: <dl class=”table”> <dt><samp class=”option”>datapath</samp></dt> <dd> Set datapath to tesseract data. Default is to use whatever was set at installation. </dd> <dt><samp class=”option”>language</samp></dt> <dd> Set language, default is "eng". </dd> <dt><samp class=”option”>whitelist</samp></dt> <dd> Set character whitelist. </dd> <dt><samp class=”option”>blacklist</samp></dt> <dd> Set character blacklist. </dd> </dl>

The filter exports recognized text as the frame metadata <code class=”code”>lavfi.ocr.text</code>. The filter exports confidence of recognized words as the frame metadata <code class=”code”>lavfi.ocr.confidence</code>. <h3 class=”section”>39.187 ocv# TOC</h3>

Apply a video transform using libopencv. To enable this filter, install the libopencv library and headers and configure FFmpeg with <code class=”code”>--enable-libopencv</code>. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>filter_name</samp></dt> <dd> The name of the libopencv filter to apply. </dd> <dt><samp class=”option”>filter_params</samp></dt> <dd> The parameters to pass to the libopencv filter. If not specified, the default values are assumed. </dd> </dl>

Refer to the official libopencv documentation for more precise information: <a class=”url” href=”http://docs.opencv.org/master/modules/imgproc/doc/filtering.html”>http://docs.open Several libopencv filters are supported; see the following subsections. <h4 class=”subsection”>39.187.1 dilate# TOC</h4>

Dilate an image by using a specific structuring element. It corresponds to the libopencv function <code class=”code”>cvDilate</code>. It accepts the parameters: <var class=”var”>struct_el</var>|<var class=”var”>nb_iterations</var>. <var class=”var”>struct_el</var> represents a structuring element, and has the syntax: <var class=”var”>cols</var>x<var

class=”var”>rows</var>+<var class=”var”>anchor_x</var>x<var class=”var”>anchor_y</var>/<var class=”var”>shape</var> <var class=”var”>cols</var> and <var class=”var”>rows</var> represent the number of columns and rows of the structuring element, <var class=”var”>anchor_x</var> and <var class=”var”>anchor_y</var> the anchor point, and <var class=”var”>shape</var> the shape for the structuring element. <var class=”var”>shape</var> must be "rect", "cross", "ellipse", or "custom". If the value for <var class=”var”>shape</var> is "custom", it must be followed by a string of the form "=<var class=”var”>filename</var>". The file with name <var class=”var”>filename</var> is assumed to represent a binary image, with each printable character corresponding to a bright pixel. When a custom <var class=”var”>shape</var> is used, <var class=”var”>cols</var> and <var class=”var”>rows</var> are ignored, the number or columns and rows of the read file are assumed instead. The default value for <var class=”var”>struct_el</var> is "3x3+0x0/rect". <var class=”var”>nb_iterations</var> specifies the number of times the transform is applied to the image, and defaults to 1. Some examples: <pre class=”example-preformatted”># Use the default values ocv=dilate

Dilate using a structuring element with a 5x5 cross, iterating two times ocv=filter_name=dilate:filter_params=5x5+2x2/cross|2

Read the shape from the file diamond.shape, iterating two times. # The file diamond.shape may contain a pattern of characters like this # * # *** # ***** # *** # * # The specified columns and rows are ignored # but the anchor point coordinates are not ocv=dilate:0x0+2x2/custom=diamond.shape|2 </pre>

 <h4 class=”subsection”>39.187.2 erode# TOC</h4>

Erode an image by using a specific structuring element. It corresponds to the libopencv function <code class=”code”>cvErode</code>. It accepts the parameters: <var class=”var”>struct_el</var>:<var class=”var”>nb_iterations</var>, with the same syntax and semantics as the dilate filter. <h4 class=”subsection”>39.187.3 smooth# TOC</h4>

Smooth the input video. The filter takes the following parameters: <var class=”var”>type</var>|<var class=”var”>param1</var>|<var class=”var”>param2</var>|<var class=”var”>param3</var>|<var class=”var”>param4</var>.

 <var class="var">type</var> is the type of smooth filter to apply, and must be one of the following values: "blur", "blur_no_scale", "median", "gaussian", or "bilateral". The default value is "gaussian". The meaning of <var class="var">param1</var>, <var class="var">param2</var>, <var class="var">param3</var>, and <var class="var">param4</var> depends on the smooth type. <var class="var">param1</var> and <var class="var">param2</var> accept integer positive values or 0. <var class="var">param3</var> and <var class="var">param4</var> accept floating point values. The default value for <var class="var">param1</var> is 3. The default value for the other parameters is 0. These parameters correspond to the parameters assigned to the libopencv function <code class="code">cvSmooth</code>. <h3 class="section">39.188 oscilloscope# TOC</h3>

2D Video Oscilloscope. Useful to measure spatial impulse, step responses, chroma delays, etc. It accepts the following parameters: <dl class="table"> <dt><samp class="option">x</samp></dt> <dd> Set scope center x position. </dd> <dt><samp class="option">y</samp></dt> <dd> Set scope center y position. </dd> <dt><samp class="option">s</samp></dt> <dd> Set scope size, relative to frame diagonal. </dd> <dt><samp class="option">t</samp></dt> <dd> Set scope tilt/rotation. </dd> <dt><samp class="option">o</samp></dt> <dd> Set trace opacity. </dd> <dt><samp class="option">tx</samp></dt> <dd> Set trace center x position. </dd> <dt><samp class="option">ty</samp></dt> <dd> Set trace center y position. </dd> <dt><samp class="option">tw</samp></dt> <dd> Set trace width, relative to width of frame. </dd> <dt><samp class="option">th</samp></dt> <dd> Set trace height, relative to height of frame. </dd> <dt><samp class="option">c</samp></dt> <dd> Set which components to trace. and <var class="var">vsub</var> is 1. </dd> <dt><samp
class="option">n</samp></dt> <dd> the number of input frame, start-
ing from 0 </dd> <dt><samp class="option">pos</samp></dt>
<dd> the position in the file of the input frame, NAN if unknown; depre-
cated, do not use </dd> <dt><samp class="option">t</samp></dt>

<dd> The timestamp, expressed in seconds. It’s NAN if the input timestamp is unknown. </dd> </dl>

This filter also supports the framesync options. Note that the <var class="var">n</var>, <var class="var">t</var> variables are available only when evaluation is done per frame, and will evaluate to NAN when <samp class="option">eval</samp> is set to ‘<samp class="samp">init</samp>’. Be aware that frames are taken from each input video in timestamp order, hence, if their initial timestamps differ, it is a good idea to pass the two inputs through a <var class="var">setpts=PTS-STARTPTS</var> filter to have them begin in the same zero timestamp, as the example for the <var class="var">movie</var> filter does. You can chain together more overlays but you should test the efficiency of such approach. <h4 class="subsection">39.189.1 Commands# TOC</h4>

This filter supports the following commands: <dl class="table"> <dt><samp class="option">x</samp></dt> <dt><samp class="option">y</samp></dt> <dd> Modify the x and y of the overlay input. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h4 class="subsection">39.189.2 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Draw the overlay at 10 pixels from the bottom right corner of the main video: <pre class="example-preformatted">overlay=main_w-overlay_w-10:main_h-overlay_h-10 </pre>

Using named options the example above becomes: <pre class="example-preformatted">overlay=x=main_w-overlay_w-10:y=main_h-overlay_h-10 </pre>

Insert a transparent PNG logo in the bottom left corner of the input, using the <code class="command">ffmpeg</code> tool with the <code class="code">-filter_complex</code> option: <pre class="example-preformatted">ffmpeg -i input -i logo -filter_complex 'overlay=10:main_h-overlay_h-10' output </pre>

Insert 2 different transparent PNG logos (second logo on bottom right corner) using the <code class="command">ffmpeg</code> tool: <pre class="example-preformatted">ffmpeg -i input -i

logo1 -i logo2 -filter_complex 'overlay=x=10:y=H-h-10,overlay=x=W-w-10:y=H-h-10' output </pre>

Add a transparent color layer on top of the main video; <code class="code">WxH</code> must specify the size of the main input to the overlay filter: <pre class="example-preformatted">color=color=red@.3:size=WxH [over]; [in][over] overlay [out] </pre>

Play an original video and a filtered version (here with the deshake filter) side by side using the <code class="command">ffplay</code> tool: <pre class="example-preformatted">ffplay input.avi -vf 'split[a][b]; [a]pad=iw*2:ih[src]; [b]deshake[filt]; [src][filt]overlay=w' </pre>

The above command is the same as: <pre class="example-preformatted">ffplay input.avi -vf 'split[b], pad=iw*2[src], [b]deshake, [src]overlay=w' </pre>

Make a sliding overlay appearing from the left to the right top part of the screen starting since time 2: <pre class="example-preformatted">overlay=x='if(gte(t,2), -w+(t-2)*20, NAN)':y=0 </pre>

Compose output by putting two input videos side to side: <pre class="example-preformatted">ffmpeg -i left.avi -i right.avi -filter_complex " nullsrc=size=200x100 [background]; [0:v] setpts=PTS-STARTPTS, scale=100x100 [left]; [1:v] setpts=PTS-STARTPTS, scale=100x100 [right]; [background][left] overlay=shortest=1 [background+left]; [background+left][right] overlay=shortest=1:x=100 [left+right] " </pre>

Mask 10-20 seconds of a video by applying the delogo filter to a section <pre class="example-preformatted">ffmpeg -i test.avi -codec:v:0 wmv2 -ar 11025 -b:v 9000k -vf '[in]split[split_main][split_delogo];[split_delogo]trim=start=360:end=
masked.avi </pre>

Chain several overlays in cascade: <pre class="example-preformatted">nullsrc=s=200x200 [bg]; testsrc=s=100x100, split=4 [in0][in1][in2][in3]; [in0] lutrgb=r=0, [bg] overlay=0:0 [mid0]; [in1] lutrgb=g=0, [mid0] overlay=100:0 [mid1]; [in2] lutrgb=b=0, [mid1] overlay=0:100 [mid2]; [in3] null, [mid2] overlay=100:100 [out0] </pre>

 <h3 class="section">39.190 owdenoise# TOC</h3>

Apply Overcomplete Wavelet denoiser. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>depth</samp></dt> <dd> Set depth. Larger depth values will denoise lower frequency components more, but slow down filtering. Must be an int in the range 8-16, default is <code class=”code”>8</code>. </dd> <dt><samp class=”option”>luma_strength, ls</samp></dt> <dd> Set luma strength. Must be a double value in the range 0-1000, default is <code class=”code”>1.0</code>. </dd> <dt><samp class=”option”>chroma_strength, cs</samp></dt> <dd> Set chroma strength. Must be a double value in the range 0-1000, default is <code class=”code”>1.0</code>. </dd> </dl>

 <h3 class=”section”>39.191 pad# TOC</h3>

Add paddings to the input image, and place the original input at the provided <var class=”var”>x</var>, <var class=”var”>y</var> coordinates. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>width, w</samp></dt> <dt><samp class=”option”>height, h</samp></dt> <dd> Specify an expression for the size of the output image with the paddings added. If the value for <var class=”var”>width</var> or <var class=”var”>height</var> is 0, the corresponding input size is used for the output. The <var class=”var”>width</var> expression can reference the value set by the <var class=”var”>height</var> expression, and vice versa. The default value of <var class=”var”>width</var> and <var class=”var”>height</var> is 0. </dd> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> Specify the offsets to place the input image at within the padded area, with respect to the top/left border of the output image. The <var class=”var”>x</var> expression can reference the value set by the <var class=”var”>y</var> expression, and vice versa. The default value of <var class=”var”>x</var> and <var class=”var”>y</var> is 0. If <var class=”var”>x</var> or <var class=”var”>y</var> evaluate to a negative number, they’ll be changed so the input image is centered on the padded area. </dd> <dt><samp class=”option”>color</samp></dt> <dd> Specify the color of the padded area. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. The default value of <var class=”var”>color</var> is "black". </dd> <dt><samp class=”option”>eval</samp></dt> <dd> Specify when to evaluate <var class=”var”>width</var>, <var class=”var”>height</var>, <var class=”var”>x</var> and <var class=”var”>y</var> expression. It accepts the following values: <dl class=”table”>

<dt>‘<samp class="samp">init</samp>’</dt> <dd> Only evaluate expressions once during the filter initialization or when a command is processed. </dd> <dt>‘<samp class="samp">frame</samp>’</dt> <dd> Evaluate expressions for each incoming frame. </dd> </dl>

Default value is ‘<samp class="samp">init</samp>’. </dd> <dt><samp class="option">aspect</samp></dt> <dd> Pad to aspect instead to a resolution. </dd> </dl>

The value for the <var class="var">width</var>, <var class="var">height</var>, <var class="var">x</var>, and <var class="var">y</var> options are expressions containing the following constants: <dl class="table"> <dt><samp class="option">in_w</samp></dt> <dt><samp class="option">in_h</samp></dt> <dd> The input video width and height. </dd> <dt><samp class="option">iw</samp></dt> <dt><samp class="option">ih</samp></dt> <dd> These are the same as <var class="var">in_w</var> and <var class="var">in_h</var>. </dd> <dt><samp class="option">out_w</samp></dt> <dt><samp class="option">out_h</samp></dt> <dd> The output width and height (the size of the padded area), as specified by the <var class="var">width</var> and <var class="var">height</var> expressions. </dd> <dt><samp class="option">ow</samp></dt> <dt><samp class="option">oh</samp></dt> <dd> These are the same as <var class="var">out_w</var> and <var class="var">out_h</var>. </dd> <dt><samp class="option">x</samp></dt> <dt><samp class="option">y</samp></dt> <dd> The x and y offsets as specified by the <var class="var">x</var> and <var class="var">y</var> expressions, or NAN if not yet specified. </dd> <dt><samp class="option">a</samp></dt> <dd> same as <var class="var">iw</var> / <var class="var">ih</var> </dd> <dt><samp class="option">sar</samp></dt> <dd> input sample aspect ratio </dd> <dt><samp class="option">dar</samp></dt> <dd> input display aspect ratio, it is the same as (<var class="var">iw</var> / <var class="var">ih</var>) * <var class="var">sar</var> </dd> <dt><samp class="option">hsub</samp></dt> <dt><samp class="option">vsub</samp></dt> <dd> The horizontal and vertical chroma subsample values. For example for the pixel format "yuv422p" <var class="var">hsub</var> is 2 and <var class="var">vsub</var> is 1. </dd> </dl>

 <h4 class="subsection">39.191.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Add paddings with the color "violet" to the input video. The output video size is 640x480, and the top-left corner of the input video is placed at column 0, row 40 <pre class="example-preformatted">pad=640:480:0:40:violet
</pre>

The example above is equivalent to the following command: <pre class=”example-preformatted”>pad=width=640:height=480:x=0:y=40:color=violet </pre>

Pad the input to get an output with dimensions increased by 3/2, and put the input video at the center of the padded area: <pre class=”example-preformatted”>pad="3/2*iw:3/2*ih:(ow-iw)/2:(oh-ih)/2" </pre>

Pad the input to get a squared output with size equal to the maximum value between the input width and height, and put the input video at the center of the padded area: <pre class=”example-preformatted”>pad="max(iw\,ih):ow:(ow-iw)/2:(oh-ih)/2" </pre>

Pad the input to get a final w/h ratio of 16:9: <pre class=”example-preformatted”>pad="ih*16/9:ih:(ow-iw)/2:(oh-ih)/2" </pre>

In case of anamorphic video, in order to set the output display aspect correctly, it is necessary to use <var class=”var”>sar</var> in the expression, according to the relation: <pre class=”example-preformatted”>(ih * X / ih) * sar = output_dar X = output_dar / sar </pre>

Thus the previous example needs to be modified to: <pre class=”example-preformatted”>pad="ih*16/9/sar:ih:(ow-iw)/2:(oh-ih)/2" </pre>

Double the output size and put the input video in the bottom-right corner of the output padded area: <pre class=”example-preformatted”>pad="2*iw:2*ih:ow-iw:oh-ih" </pre>

 <h3 class=”section”>39.192 palettegen# TOC</h3>

Generate one palette for a whole video stream. It accepts the following options: <dl class=”table”> <dt><samp class=”option”>max_colors</samp></dt> <dd> Set the maximum number of colors to quantize in the palette. Note: the palette will still contain 256 colors; the unused palette entries will be black. </dd> <dt><samp class=”option”>reserve_transparent</samp></dt> <dd> Create a palette of 255 colors maximum and reserve the last one for transparency. Reserving the transparency color is useful for GIF optimization. If not set, the maximum of colors in the palette will be 256. You probably want to disable this option for a standalone image. Set by default. </dd> <dt><samp class=”option”>transparency_color</samp></dt> <dd> Set the color

that will be used as background for transparency. </dd> <dt><samp class="option">stats_mode</samp></dt> <dd> Set statistics mode. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">full</samp>’</dt> <dd> Compute full frame histograms. </dd> <dt>‘<samp class="samp">diff</samp>’</dt> <dd> Compute histograms only for the part that differs from previous frame. This might be relevant to give more importance to the moving part of your input if the background is static. </dd> <dt>‘<samp class="samp">single</samp>’</dt> <dd> Compute new histogram for each frame. </dd> </dl>

Default value is <var class="var">full</var>. </dd> </dl>

The filter also exports the frame metadata <code class="code">lavfi.color_quant_ratio</code> (<code class="code">nb_color_in / nb_color_out</code>) which you can use to evaluate the degree of color quantization of the palette. This information is also visible at <var class="var">info</var> logging level. <h4 class="subsection">39.192.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Generate a representative palette of a given video using <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -i input.mkv -vf palettegen palette.png </pre>

 <h3 class="section">39.193 paletteuse# TOC</h3>

Use a palette to downsample an input video stream. The filter takes two inputs: one video stream and a palette. The palette must be a 256 pixels image. It accepts the following options: <dl class="table"> <dt><samp class="option">dither</samp></dt> <dd> Select dithering mode. Available algorithms are: <dl class="table"> <dt>‘<samp class="samp">bayer</samp>’</dt> <dd> Ordered 8x8 bayer dithering (deterministic) </dd> <dt>‘<samp class="samp">heckbert</samp>’</dt> <dd> Dithering as defined by Paul Heckbert in 1982 (simple error diffusion). Note: this dithering is sometimes considered "wrong" and is included as a reference. </dd> <dt>‘<samp class="samp">floyd_steinberg</samp>’</dt> <dd> Floyd and Steingberg dithering (error diffusion) </dd> <dt>‘<samp class="samp">sierra2</samp>’</dt> <dd> Frankie Sierra dithering v2 (error diffusion) </dd> <dt>‘<samp class="samp">sierra2_4a</samp>’</dt> <dd> Frankie Sierra dithering v2 "Lite" (error diffusion) </dd>

<dt>‘<samp class="samp">sierra3</samp>’</dt> <dd> Frankie Sierra dithering v3 (error diffusion) </dd> <dt>‘<samp class="samp">burkes</samp>’</dt> <dd> Burkes dithering (error diffusion) </dd> <dt>‘<samp class="samp">atkinson</samp>’</dt> <dd> Atkinson dithering by Bill Atkinson at Apple Computer (error diffusion) </dd> <dt>‘<samp class="samp">none</samp>’</dt> <dd> Disable dithering. </dd> </dl>

Default is <var class="var">sierra2_4a</var>. </dd> <dt><samp class="option">bayer_scale</samp></dt> <dd> When <var class="var">bayer</var> dithering is selected, this option defines the scale of the pattern (how much the crosshatch pattern is visible). A low value means more visible pattern for less banding, and higher value means less visible pattern at the cost of more banding. The option must be an integer value in the range [0,5]. Default is <var class="var">2</var>. </dd> <dt><samp class="option">diff_mode</samp></dt> <dd> If set, define the zone to process <dl class="table"> <dt>‘<samp class="samp">rectangle</samp>’</dt> <dd> Only the changing rectangle will be reprocessed. This is similar to GIF cropping/offsetting compression mechanism. This option can be useful for speed if only a part of the image is changing, and has use cases such as limiting the scope of the error diffusal <samp class="option">dither</samp> to the rectangle that bounds the moving scene (it leads to more deterministic output if the scene doesn’t change much, and as a result less moving noise and better GIF compression). </dd> </dl>

Default is <var class="var">none</var>. </dd> <dt><samp class="option">new</samp></dt> <dd> Take new palette for each output frame. </dd> <dt><samp class="option">alpha_threshold</samp></dt> <dd> Sets the alpha threshold for transparency. Alpha values above this threshold will be treated as completely opaque, and values below this threshold will be treated as completely transparent. The option must be an integer value in the range [0,255]. Default is <var class="var">128</var>. </dd> </dl>

 <h4 class="subsection">39.193.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Use a palette (generated for example with palettegen) to encode a GIF using <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -i input.mkv -i palette.png -lavfi paletteuse output.gif </pre>

 <h3 class="section">39.195 phase<span class="pull-
right">#
TOC</h3>

Delay interlaced video by one field time so that the field order changes.
 The intended use is to fix PAL movies that have been captured
with the opposite field order to the film-to-video transfer. A
description of the accepted parameters follows. <dl class="table">
<dt><samp class="option">mode</samp></dt> <dd> Set phase
mode. It accepts the following values: <dl class="table">
<dt>‘<samp class="samp">t</samp>’</dt> <dd> Capture
field order top-first, transfer bottom-first. Filter will delay the bottom field.
 </dd> <dt>‘<samp class="samp">b</samp>’</dt>
<dd> Capture field order bottom-first, transfer top-first. Filter will delay
the top field. </dd> <dt>‘<samp class="samp">p</samp>’</dt>
<dd> Capture and transfer with the same field order. This mode only
exists for the documentation of the other options to refer to, but if you actually
select it, the filter will faithfully do nothing. </dd> <dt>‘<samp
class="samp">a</samp>’</dt> <dd> Capture field or-
der determined automatically by field flags, transfer opposite. Filter
selects among ‘<samp class="samp">t</samp>’ and
‘<samp class="samp">b</samp>’ modes on a frame by
frame basis using field flags. If no field information is available, then
this works just like ‘<samp class="samp">u</samp>’.
 </dd> <dt>‘<samp class="samp">u</samp>’</dt>
<dd> Capture unknown or varying, transfer opposite. Filter selects
among ‘<samp class="samp">t</samp>’ and ‘<samp
class="samp">b</samp>’ on a frame by frame basis by analyzing the
images and selecting the alternative that produces best match between the fields.
 </dd> <dt>‘<samp class="samp">T</samp>’</dt>
<dd> Capture top-first, transfer unknown or varying. Filter selects
among ‘<samp class="samp">t</samp>’ and ‘<samp
class="samp">p</samp>’ using image analysis. </dd>
<dt>‘<samp class="samp">B</samp>’</dt> <dd> Capture
bottom-first, transfer unknown or varying. Filter selects among ‘<samp
class="samp">b</samp>’ and ‘<samp class="samp">p</samp>’
using image analysis. </dd> <dt>‘<samp class="samp">A</samp>’</dt>
<dd> Capture determined by field flags, transfer unknown or varying.
Filter selects among ‘<samp class="samp">t</samp>’,
‘<samp class="samp">b</samp>’ and ‘<samp
class="samp">p</samp>’ using field flags and image analysis. If
no field information is available, then this works just like ‘<samp
class="samp">U</samp>’. This is the default mode.
</dd> <dt>‘<samp class="samp">U</samp>’</dt>

<dd> Both capture and transfer unknown or varying. Filter selects among ‘<samp class="samp">t</samp>’, ‘<samp class="samp">b</samp>’ and ‘<samp class="samp">p</samp>’ using image analysis only. </dd> </dl> </dd> </dl>

All expressions default to "val". <h4 class="subsection">39.204.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h4 class="subsection">39.204.2 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Change too high luma values to gradient: <pre class="example-preformatted">pseudocolor="'if(between(val,ymax,amax) ymax)/(amax-ymax)),-1):if(between(val,ymax,amax),lerp(umax,umin,(val-ymax)/(amax-ymax)),-1):if(between(val,ymax,amax),lerp(vmin,vmax,(val-ymax)/(amax-ymax)),-1):-1'" </pre>

 <h3 class="section">39.205 psnr# TOC</h3>

Obtain the average, maximum and minimum PSNR (Peak Signal to Noise Ratio) between two input videos. This filter takes in input two input videos, the first input is considered the "main" source and is passed unchanged to the output. The second input is used as a "reference" video for computing the PSNR. Both video inputs must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained average PSNR is printed through the logging system. The filter stores the accumulated MSE (mean squared error) of each frame, and at the end of the processing it is averaged across all frames equally, and the following formula is applied to obtain the PSNR: <pre class="example-preformatted">PSNR = 10*log10(MAX^2/MSE) </pre>

Where MAX is the average of the maximum values of each component of the image. The description of the accepted parameters follows. <dl class="table"> <dt><samp class="option">stats_file, f</samp></dt> <dd> If specified the filter will use the named file to save the PSNR of each individual frame. When filename equals "-" the data is sent to standard output. </dd> <dt><samp class="option">stats_version</samp></dt> <dd> Specifies which version of the stats file format to use. Details of each format are written below. Default value is 1. </dd> <dt><samp class="option">output_max</samp></dt> <dd> Determines whether the max value is output to the stats log. Default value is 0. Requires stats_version >= 2. If this is set and stats_version < 2, the filter will return an error. </dd> </dl>

This filter also supports the framesync options. The file printed if <var class="var">stats_file</var> is selected, contains a sequence of key/value pairs of the form <var class="var">key</var>:<var class="var">value</var> for each compared couple of frames. If a <var class="var">stats_version</var> greater than 1 is specified, a header line precedes the list of per-frame-pair stats, with key value pairs following the frame format with the following parameters: <dl class="table"> <dt><samp class="option">psnr_log_version</samp></dt> <dd> The version of the log file format. Will match <var class="var">stats_version</var>. </dd> <dt><samp class="option">fields</samp></dt> <dd> A comma separated list of the per-frame-pair parameters included in the log. </dd> </dl>

A description of each shown per-frame-pair parameter follows: <dl class="table"> <dt><samp class="option">n</samp></dt> <dd> sequential number of the input frame, starting from 1 </dd> <dt><samp class="option">mse_avg</samp></dt> <dd> Mean Square Error pixel-by-pixel average difference of the compared frames, averaged over all the image components. </dd> <dt><samp class="option">mse_y, mse_u, mse_v, mse_r, mse_g, mse_b, mse_a</samp></dt> <dd> Mean Square Error pixel-by-pixel average difference of the compared frames for the component specified by the suffix. </dd> <dt><samp class="option">psnr_y, psnr_u, psnr_v, psnr_r, psnr_g, psnr_b, psnr_a</samp></dt> <dd> Peak Signal to Noise ratio of the compared frames for the component specified by the suffix. </dd> <dt><samp class="option">max_avg, max_y, max_u, max_v</samp></dt> <dd> Maximum allowed value for each channel, and average over all channels. </dd> </dl>

 <h4 class="subsection">39.205.1 Examples# TOC</h4> <ul class="itemize mark-bullet"> For example: <pre class="example-preformatted">movie=ref_movie.mpg, setpts=PTS-STARTPTS [main];

[main][ref] psnr="stats_file=stats.log" [out] </pre>

On this example the input file being processed is compared with the reference file <samp class="file">ref_movie.mpg</samp>. The PSNR of each individual frame is stored in <samp class="file">stats.log</samp>. Another example with different containers: <pre class="example-preformatted">ffmpeg -i main.mpg -i ref.mkv -lavfi "[0:v]settb=AVTB,setpts=PTS-STARTPTS[main];[1:v]settb=AVTB,setpts=PTS-STARTPTS[ref];[main][ref]psnr" -f null - </pre>

 <h3 class="section">39.206 pullup# TOC</h3>

Pulldown reversal (inverse telecine) filter, capable of handling mixed hard-telecine, 24000/1001 fps progressive, and 30000/1001 fps progressive content. The pullup filter is designed to take advantage of future context in making its decisions. This filter is stateless in the sense that it does not lock onto a pattern to follow, but it instead looks forward to the following fields in order to identify matches and rebuild progressive frames. To produce content with an even framerate, insert the fps filter after pullup, use <code class="code">fps=24000/1001</code> if the input frame rate is 29.97fps, <code class="code">fps=24</code> for 30fps and the (rare) telecined 25fps input. The filter accepts the following options: <dl class="table"> <dt><samp class="option">jl</samp></dt> <dt><samp class="option">jr</samp></dt> <dt><samp class="option">jt</samp></dt> <dt><samp class="option">jb</samp></dt> <dd> These options set the amount of "junk" to ignore at the left, right, top, and bottom of the image, respectively. Left and right are in units of 8 pixels, while top and bottom are in units of 2 lines. The default is 8 pixels on each side. </dd> <dt><samp class="option">sb</samp></dt> <dd> Set the strict breaks. Setting this option to 1 will reduce the chances of filter generating an occasional mismatched frame, but it may also cause an excessive number of frames to be dropped during high motion sequences. Conversely, setting it to -1 will make filter match fields more easily. This may help processing of video where there is slight blurring between the fields, but may also cause there to be interlaced frames in the output. Default value is <code class="code">0</code>. </dd> <dt><samp class="option">mp</samp></dt> <dd> Set the metric plane to use. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">l</samp>’</dt> <dd> Use luma plane. </dd> <dt>‘<samp class="samp">u</samp>’</dt> <dd> Use chroma blue plane. </dd> <dt>‘<samp class="samp">v</samp>’</dt> <dd> Use chroma red plane. </dd> </dl>

This option may be set to use chroma plane instead of the default luma

plane for doing filter’s computations. This may improve accuracy on very clean source material, but more likely will decrease accuracy, especially if there is chroma noise (rainbow effect) or any grayscale video. The main purpose of setting <samp class="option">mp</samp> to a chroma plane is to reduce CPU load and make pullup usable in realtime on slow machines. </dd> </dl>

For best results (without duplicated frames in the output file) it is necessary to change the output frame rate. For example, to inverse telecine NTSC input: <pre class="example-preformatted">ffmpeg -i input -vf pullup -r 24000/1001 ... </pre>

 <h3 class="section">39.207 qp# TOC</h3>

Change video quantization parameters (QP). The filter accepts the following option: <dl class="table"> <dt><samp class="option">qp</samp></dt> <dd> Set expression for quantization parameter. </dd> </dl>

The expression is evaluated through the eval API and can contain, among others, the following constants: <dl class="table"> <dt><var class="var">known</var></dt> <dd> 1 if index is not 129, 0 otherwise. </dd> <dt><var class="var">qp</var></dt> <dd> Sequential index starting from -129 to 128. </dd> </dl>

These parameters allow the <var class="var">x</var> and <var class="var">y</var> expressions to refer to each other, so you can for example specify <code class="code">y=x/dar</code>. </dd> </dl>

<a

name=”qrencode-Text-expansion”> <h4 class=”subsection”>39.208.2 qrencode Text expansion# TOC</h4>

If <samp class=”option”>expansion</samp> is set to <code class=”code”>none</code>, the text is printed verbatim. If <samp class=”option”>expansion</samp> is set to <code class=”code”>normal</code> (which is the default), the following expansion mechanism is used. The backslash character ‘<samp class=”samp”>\</samp>’, followed by any character, always expands to the second character. Sequences of the form <code class=”code”>%{...}</code> are expanded. The text between the braces is a function name, possibly followed by arguments separated by ’:’. If the arguments contain special characters or delimiters (’:’ or ’}’), they should be escaped. Note that they probably must also be escaped as the value for the <samp class=”option”>text</samp> option in the filter argument string and as the filter argument in the filtergraph description, and possibly also for the shell, that makes up to four levels of escaping; using a text file with the <samp class=”option”>textfile</samp> option avoids these problems. The following functions are available: <dl class=”table”> <dt><code class=”command”>n, frame_num</code></dt> <dd> return the frame number </dd> <dt><code class=”command”>pts</code></dt> <dd> Return the presentation timestamp of the current frame. It can take up to two arguments. The first argument is the format of the timestamp; it defaults to <code class=”code”>flt</code> for seconds as a decimal number with microsecond accuracy; <code class=”code”>hms</code> stands for a formatted <var class=”var”>[-]HH:MM:SS.mmm</var> timestamp with millisecond accuracy. <code class=”code”>gmtime</code> stands for the timestamp of the frame formatted as UTC time; <code class=”code”>localtime</code> stands for the timestamp of the frame formatted as local time zone time. If the format is set to <code class=”code”>hms24hh</code>, the time is formatted in 24h format (00-23). The second argument is an offset added to the timestamp. If the format is set to <code class=”code”>localtime</code> or <code class=”code”>gmtime</code>, a third argument may be supplied: a <code class=”code”>strftime</code> C function format string. By default, <var class=”var”>YYYY-MM-DD HH:MM:SS</var> format will be used. </dd> <dt><code class=”command”>expr, e</code></dt> <dd> Evaluate the expression’s value and output as a double. It must take one argument specifying the expression to be evaluated, accepting the constants and functions defined in qrencode_expressions. </dd> <dt><code class=”command”>expr_formatted, ef</code></dt> <dd> Evaluate the expression’s value and output as a formatted string. The first argument is the expression to

be evaluated, just as for the <var class=”var”>expr</var> function. The second argument specifies the output format. Allowed values are ‘<samp class=”samp”>x</samp>’, ‘<samp class=”samp”>X</samp>’, ‘<samp class=”samp”>d</samp>’ and ‘<samp class=”samp”>u</samp>’. They are treated exactly as in the <code class=”code”>printf</code> function. The third parameter is optional and sets the number of positions taken by the output. It can be used to add padding with zeros from the left. </dd> <dt><code class=”command”>gmtime</code></dt> <dd> The time at which the filter is running, expressed in UTC. It can accept an argument: a <code class=”code”>strftime</code> C function format string. The format string is extended to support the variable <var class=”var”>%[1-6]N</var> which prints fractions of the second with optionally specified number of digits. </dd> <dt><code class=”command”>localtime</code></dt> <dd> The time at which the filter is running, expressed in the local time zone. It can accept an argument: a <code class=”code”>strftime</code> C function format string. The format string is extended to support the variable <var class=”var”>%[1-6]N</var> which prints fractions of the second with optionally specified number of digits. </dd> <dt><code class=”command”>metadata</code></dt> <dd> Frame metadata. Takes one or two arguments. The first argument is mandatory and specifies the metadata key. The second argument is optional and specifies a default value, used when the metadata key is not found or empty. Available metadata can be identified by inspecting entries starting with TAG included within each frame section printed by running <code class=”code”>ffprobe -show_frames</code>. String metadata generated in filters leading to the qrencode filter are also available. </dd> <dt><code class=”command”>rand(min, max)</code></dt> <dd> return a random number included between <var class=”var”>min</var> and <var class=”var”>max</var> </dd> </dl>

 <h3 class=”section”>39.215 removelogo# TOC</h3>

Suppress a TV station logo, using an image file to determine which pixels comprise the logo. It works by filling in the pixels that comprise the logo with neighboring pixels. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>filename, f</samp></dt> <dd> Set the filter bitmap file, which can be any image format supported by libavformat. The width and height of the image file must match those of the video stream being processed. </dd> </dl>

Pixels in the provided bitmap image with a value of zero are not considered part of the logo, non-zero pixels are considered part of the logo. If you use

white (255) for the logo and black (0) for the rest, you will be safe. For making the filter bitmap, it is recommended to take a screen capture of a black frame with the logo visible, and then using a threshold filter followed by the erode filter once or twice. If needed, little splotches can be fixed manually. Remember that if logo pixels are not covered, the filter quality will be much reduced. Marking too many pixels as part of the logo does not hurt as much, but it will increase the amount of blurring needed to cover over the image and will destroy more information than necessary, and extra pixels will slow things down on a large logo. <h3 class="section">39.216 repeatfields# TOC</h3>

This filter uses the repeat_field flag from the Video ES headers and hard repeats fields based on its value. <h3 class="section">39.217 reverse# TOC</h3>

Reverse a video clip. Warning: This filter requires memory to buffer the entire clip, so trimming is suggested. <h4 class="subsection">39.217.1 Examples# TOC</h4>

The filter accepts the following option: <dl class="table"> <dt><samp class="option">planes</samp></dt> <dd> Set which planes will be processed, unprocessed planes will be copied. By default value 0xf, all planes will be processed. </dd> <dt><samp class="option">scale</samp></dt> <dd> Set value which will be multiplied with filtered result. </dd> <dt><samp class="option">delta</samp></dt> <dd> Set value which will be added to filtered result. </dd> </dl>

 <h4 class="subsection">39.219.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">39.220 rotate# TOC</h3>

Rotate video by an arbitrary angle expressed in radians. The filter accepts the following options: A description of the optional parameters follows. <dl class="table"> <dt><samp class="option">angle, a</samp></dt> <dd> Set an expression for the angle by which to rotate the input video clockwise, expressed as a number of radians. A negative value will result in a counter-clockwise rotation. By default it is set to "0". This expression is evaluated for each frame. </dd> <dt><samp class="option">out_w, ow</samp></dt> <dd> Set the output width expression, default value is "iw". This expression is evaluated just once during configuration. </dd> <dt><samp class="option">out_h, oh</samp></dt> <dd> Set the output height expression, default value is "ih". This expression is evaluated just once during configuration. </dd> <dt><samp class="option">bilinear</samp></dt> <dd> Enable bilinear interpo-

lation if set to 1, a value of 0 disables it. Default value is 1. </dd> <dt><samp class=”option”>fillcolor, c</samp></dt> <dd> Set the color used to fill the output area not covered by the rotated image. For the general syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. If the special value "none" is selected then no background is printed (useful for example if the background is never shown). Default value is "black". </dd> </dl>

The expressions for the angle and the output size can contain the following constants and functions: <dl class=”table”> <dt><samp class=”option”>n</samp></dt> <dd> sequential number of the input frame, starting from 0. It is always NAN before the first frame is filtered. </dd> <dt><samp class=”option”>t</samp></dt> <dd> time in seconds of the input frame, it is set to 0 when the filter is configured. It is always NAN before the first frame is filtered. </dd> <dt><samp class=”option”>hsub</samp></dt> <dt><samp class=”option”>vsub</samp></dt> <dd> horizontal and vertical chroma subsample values. For example for the pixel format "yuv422p" <var class=”var”>hsub</var> is 2 and <var class=”var”>vsub</var> is 1. </dd> <dt><samp class=”option”>in_w, iw</samp></dt> <dt><samp class=”option”>in_h, ih</samp></dt> <dd> the input video width and height </dd> <dt><samp class=”option”>out_w, ow</samp></dt> <dt><samp class=”option”>out_h, oh</samp></dt> <dd> the output width and height, that is the size of the padded area as specified by the <var class=”var”>width</var> and <var class=”var”>height</var> expressions </dd> <dt><samp class=”option”>rotw(a)</samp></dt> <dt><samp class=”option”>roth(a)</samp></dt> <dd> the minimal width/height required for completely containing the input video rotated by <var class=”var”>a</var> radians. These are only available when computing the <samp class=”option”>out_w</samp> and <samp class=”option”>out_h</samp> expressions. </dd> </dl>

 <h4 class=”subsection”>39.220.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Rotate the input by PI/6 radians clockwise: <pre class=”example-preformatted”>rotate=PI/6 </pre>

Rotate the input by PI/6 radians counter-clockwise: <pre class=”example-preformatted”>rotate=-PI/6 </pre>

Rotate the input by 45 degrees clockwise: <pre class=”example-preformatted”>rotate=45*PI/180 </pre>

Apply a constant rotation with period T, starting from an angle of PI/3: <pre class=”example-preformatted”>rotate=PI/3+2*PI*t/T </pre>

Make the input video rotation oscillating with a period of T seconds and an amplitude of A radians: <pre class=”example-preformatted”>rotate=A*sin(2*PI/T*t) </pre>

Rotate the video, output size is chosen so that the whole rotating input video is always completely contained in the output: <pre class=”example-preformatted”>rotate='2*PI*t:ow=hypot(iw,ih):oh=ow' </pre>

Rotate the video, reduce the output size so that no background is ever shown: <pre class=”example-preformatted”>rotate=2*PI*t:ow='min(iw,ih)/sqrt(2)':oh=ow:c=none </pre>

 <h4 class=”subsection”>39.220.2 Commands# TOC</h4>

The filter supports the following commands: <dl class=”table”> <dt><samp class=”option”>a, angle</samp></dt> <dd> Set the angle expression. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h3 class=”section”>39.221 sab# TOC</h3>

Apply Shape Adaptive Blur. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>luma_radius, lr</samp></dt> <dd> Set luma blur filter strength, must be a value in range 0.1-4.0, default value is 1.0. A greater value will result in a more blurred image, and in slower processing. </dd> <dt><samp class=”option”>luma_pre_filter_radius, lpfr</samp></dt> <dd> Set luma pre-filter radius, must be a value in the 0.1-2.0 range, default value is 1.0. </dd> <dt><samp class=”option”>luma_strength, ls</samp></dt> <dd> Set luma maximum difference between pixels to still be considered, must be a value in the 0.1-100.0 range, default value is 1.0. </dd> <dt><samp class=”option”>chroma_radius, cr</samp></dt> <dd> Set chroma blur filter strength, must be a value in range -0.9-4.0. A greater value will result in a more blurred image, and in slower processing. </dd> <dt><samp class=”option”>chroma_pre_filter_radius, cpfr</samp></dt> <dd> Set chroma pre-filter radius, must be a value in the -0.9-2.0 range. </dd> <dt><samp class=”option”>chroma_strength,

cs</samp></dt> <dd> Set chroma maximum difference between pixels to still be considered, must be a value in the -0.9-100.0 range. </dd> </dl>

Each chroma option value, if not explicitly specified, is set to the corresponding luma option value. <h3 class="section">39.222 scale# TOC</h3>

Scale (resize) the input video, using the libswscale library. The scale filter forces the output display aspect ratio to be the same of the input, by changing the output sample aspect ratio. If the input image format is different from the format requested by the next filter, the scale filter will convert the input to the requested format. <h4 class="subsection">39.222.1 Options# TOC</h4> The filter accepts the following options, any of the options supported by the libswscale scaler, as well as any of the framesync options. See <a data-manual="ffmpeg-scaler" href="./ffmpeg-scaler.html#scaler_005foptions">the ffmpeg-scaler manual for the complete list of scaler options. <dl class="table"> <dt><samp class="option">width, w</samp></dt> <dt><samp class="option">height, h</samp></dt> <dd> Set the output video dimension expression. Default value is the input dimension. If the <var class="var">width</var> or <var class="var">w</var> value is 0, the input width is used for the output. If the <var class="var">height</var> or <var class="var">h</var> value is 0, the input height is used for the output. If one and only one of the values is -n with n >= 1, the scale filter will use a value that maintains the aspect ratio of the input image, calculated from the other specified dimension. After that it will, however, make sure that the calculated dimension is divisible by n and adjust the value if necessary. If both values are -n with n >= 1, the behavior will be identical to both values being set to 0 as previously detailed. See below for the list of accepted constants for use in the dimension expression. </dd> <dt><samp class="option">eval</samp></dt> <dd> Specify when to evaluate <var class="var">width</var> and <var class="var">height</var> expression. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">init</samp>’</dt> <dd> Only evaluate expressions once during the filter initialization or when a command is processed. </dd> <dt>‘<samp class="samp">frame</samp>’</dt> <dd> Evaluate expressions for each incoming frame. </dd> </dl>

Default value is ‘<samp class="samp">init</samp>’.

</dd> <dt><samp class=”option”>interl</samp></dt> <dd> Set the interlacing mode. It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>1</samp>’</dt> <dd> Force interlaced aware scaling. </dd> <dt>‘<samp class=”samp”>0</samp>’</dt> <dd> Do not apply interlaced scaling. </dd> <dt>‘<samp class=”samp”>-1</samp>’</dt> <dd> Select interlaced aware scaling depending on whether the source frames are flagged as interlaced or not. </dd> </dl>

Default value is ‘<samp class=”samp”>0</samp>’. </dd> <dt><samp class=”option”>flags</samp></dt> <dd> Set libswscale scaling flags. See <a data-manual=”ffmpeg-scaler” href=”./ffmpeg-scaler.html#sws_005fflags”>the ffmpeg-scaler manual for the complete list of values. If not explicitly specified the filter applies the default flags.

</dd> <dt><samp class=”option”>param0, param1</samp></dt> <dd> Set libswscale input parameters for scaling algorithms that need them. See <a data-manual=”ffmpeg-scaler” href=”./ffmpeg-scaler.html#sws_005fparams”>the ffmpeg-scaler manual for the complete documentation. If not explicitly specified the filter applies empty parameters. </dd> <dt><samp class=”option”>intent</samp></dt> <dd> Set the ICC rendering intent to use when transforming between different color spaces. It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>perceptual</samp>’</dt> <dd> Use a perceptually guided tone and gamut mapping curve. The exact details of the mapping used may change at any time and should not be relied on as stable. This intent is recommended for final viewing of image/video content in typical viewing settings. </dd> <dt>‘<samp class=”samp”>relative_colorimetric</samp>’</dt> <dd> Statically clip out-of-gamut colors using a colorimetric clipping curve which attempts to find the colorimetrically least dissimilar in-gamut color. This intent performs white point adaptation and black point adaptation. This is the default. This intent is recommended wherever faithful color reproduction is of the utmost importance, even at the cost of clipping. </dd> <dt>‘<samp class=”samp”>absolute_colorimetric</samp>’</dt> <dd> Hard clip out-of-gamut colors with no attempt at white or black point reproduction. This intent will reproduce in-gamut colors 1:1 on the output display as they would appear on the reference display, assuming the output display is appropriately calibrated. </dd> <dt>‘<samp class=”samp”>saturation</samp>’</dt> <dd> Performs saturation mapping - that is, stretches the input color volume directly onto the output color volume, in non-linear fashion that preserves the original signal appearance as much as possible. This intent is recommended for signal content evaluation, as it will not lead to any clipping. It is roughly analogous to not performing

any color mapping, although it still takes into account the mastering display primaries and any differences in encoding TRC. </dd> </dl>

</dd> <dt><samp class="option">size, s</samp></dt> <dd> Set the video size. </dd> <dt><samp class="option">force_original_aspect_ratio</samp></dt> <dd> Enable decreasing or increasing output video width or height if necessary to keep the original aspect ratio. Possible values: <dl class="table"> <dt>‘<samp class="samp">disable</samp>’</dt> <dd> Scale the video as specified and disable this feature. </dd> <dt>‘<samp class="samp">decrease</samp>’</dt> <dd> The output video dimensions will automatically be decreased if needed. </dd> <dt>‘<samp class="samp">increase</samp>’</dt> <dd> The output video dimensions will automatically be increased if needed. </dd> </dl>

One useful instance of this option is that when you know a specific device’s maximum allowed resolution, you can use this to limit the output video to that, while retaining the aspect ratio. For example, device A allows 1280x720 playback, and your video is 1920x800. Using this option (set it to decrease) and specifying 1280x720 to the command line makes the output 1280x533. Please note that this is a different thing than specifying -1 for <samp class="option">w</samp> or <samp class="option">h</samp>, you still need to specify the output resolution for this option to work. </dd> <dt><samp class="option">force_divisible_by</samp></dt> <dd> Ensures that both the output dimensions, width and height, are divisible by the given integer when used together with <samp class="option">force_original_aspect_ratio</samp>. This works similar to using <code class="code">-n</code> in the <samp class="option">w</samp> and <samp class="option">h</samp> options. This option respects the value set for <samp class="option">force_original_aspect_ratio</samp>, increasing or decreasing the resolution accordingly. The video’s aspect ratio may be slightly modified. This option can be handy if you need to have a video fit within or exceed a defined resolution using <samp class="option">force_original_aspect_ratio</samp> but also have encoder restrictions on width or height divisibility. </dd> <dt><samp class="option">reset_sar</samp></dt> <dd> Enabling this option leads to the output SAR being reset to 1. Additionally, if the user requests proportional scaling either through the width or height expressions, e.g. <code class="code">w=-4:h=360</code> or <code class="code">w=iw/2:h=-1</code> or by enabling <code class="code">force_original_aspect_ratio</code>,

then the input DAR is taken into account and the output is scaled to produce square pixels. Default is false. </dd> </dl>

 <h3 class="section">39.226 selectivecolor#
TOC</h3>

Adjust cyan, magenta, yellow and black (CMYK) to certain ranges of colors (such as "reds", "yellows", "greens", "cyans", ...). The adjustment range is defined by the "purity" of the color (that is, how saturated it already is). This filter is similar to the Adobe Photoshop Selective Color tool. The filter accepts the following options: <dl class="table"> <dt><samp class="option">correction_method</samp></dt> <dd> Select color correction method. Available values are: <dl class="table">
<dt>‘<samp class="samp">absolute</samp>’</dt> <dd> Specified adjustments are applied "as-is" (added/subtracted to original pixel component value). </dd> <dt>‘<samp class="samp">relative</samp>’</dt>
<dd> Specified adjustments are relative to the original component value. </dd> </dl> Default is <code class="code">absolute</code>. </dd> <dt><samp class="option">reds</samp></dt> <dd> Adjustments for red pixels (pixels where the red component is the maximum) </dd>
<dt><samp class="option">yellows</samp></dt> <dd> Adjustments for yellow pixels (pixels where the blue component is the minimum) </dd>
<dt><samp class="option">greens</samp></dt> <dd> Adjustments for green pixels (pixels where the green component is the maximum) </dd> <dt><samp class="option">cyans</samp></dt> <dd> Adjustments for cyan pixels (pixels where the red component is the minimum) </dd>
<dt><samp class="option">blues</samp></dt> <dd> Adjustments for blue pixels (pixels where the blue component is the maximum) </dd> <dt><samp class="option">magentas</samp></dt>
<dd> Adjustments for magenta pixels (pixels where the green component is the minimum) </dd> <dt><samp class="option">whites</samp></dt>
<dd> Adjustments for white pixels (pixels where all components are greater

than 128) </dd> <dt><samp class="option">neutrals</samp></dt> <dd> Adjustments for all pixels except pure black and pure white </dd> <dt><samp class="option">blacks</samp></dt> <dd> Adjustments for black pixels (pixels where all components are lesser than 128) </dd> <dt><samp class="option">psfile</samp></dt> <dd> Specify a Photoshop selective color file (<code class="code">.asv</code>) to import the settings from. </dd> </dl>

All the adjustment settings (<samp class="option">reds</samp>, <samp class="option">yellows</samp>, ...) accept up to 4 space separated floating point adjustment values in the [-1,1] range, respectively to adjust the amount of cyan, magenta, yellow and black for the pixels of its range. <h4 class="subsection">39.226.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Increase cyan by 50% and reduce yellow by 33% in every green areas, and increase magenta by 27% in blue areas: <pre class="example-preformatted">selectivecolor=greens=.5 0 -.33 0:blues=0 .27 </pre>

Use a Photoshop selective color preset: <pre class="example-preformatted">selectivecolor=psfile=MySelectiveColorPresets/Misty.asv </pre>

 <h3 class="section">39.227 separatefields# TOC</h3>

The <code class="code">separatefields</code> takes a frame-based video input and splits each frame into its components fields, producing a new half height clip with twice the frame rate and twice the frame count. This filter use field-dominance information in frame to decide which of each pair of fields to place first in the output. If it gets it wrong use setfield filter before <code class="code">separatefields</code> filter. <h3 class="section">39.228 setdar, setsar# TOC</h3>

The <code class="code">setdar</code> filter sets the Display Aspect Ratio for the filter output video. This is done by changing the specified Sample (aka Pixel) Aspect Ratio, according to the following equation: <pre class="example-preformatted"><var class="var">DAR</var> = <var class="var">HORIZONTAL_RESOLUTION</var>

/ <var class=”var”>VERTICAL_RESOLUTION</var> * <var class=”var”>SAR</var> </pre>

Keep in mind that the <code class=”code”>setdar</code> filter does not modify the pixel dimensions of the video frame. Also, the display aspect ratio set by this filter may be changed by later filters in the filterchain, e.g. in case of scaling or if another "setdar" or a "setsar" filter is applied. The <code class=”code”>setsar</code> filter sets the Sample (aka Pixel) Aspect Ratio for the filter output video. Note that as a consequence of the application of this filter, the output display aspect ratio will change according to the equation above. Keep in mind that the sample aspect ratio set by the <code class=”code”>setsar</code> filter may be changed by later filters in the filterchain, e.g. if another "setsar" or a "setdar" filter is applied. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>r, ratio, dar (<code class=”code”>setdar</code> only), sar (<code class=”code”>setsar</code> only)</samp></dt> <dd> Set the aspect ratio used by the filter. The parameter can be a floating point number string, or an expression. If the parameter is not specified, the value "0" is assumed, meaning that the same input value is used. </dd> <dt><samp class=”option”>max</samp></dt> <dd> Set the maximum integer value to use for expressing numerator and denominator when reducing the expressed aspect ratio to a rational. Default value is <code class=”code”>100</code>. </dd> </dl>

The parameter <var class=”var”>sar</var> is an expression containing the following constants: <dl class=”table”> <dt><samp class=”option”>w, h</samp></dt> <dd> The input width and height. </dd> <dt><samp class=”option”>a</samp></dt> <dd> Same as <var class=”var”>w</var> / <var class=”var”>h</var>. </dd> <dt><samp class=”option”>sar</samp></dt> <dd> The input sample aspect ratio. </dd> <dt><samp class=”option”>dar</samp></dt> <dd> The input display aspect ratio. It is the same as (<var class=”var”>w</var> / <var class=”var”>h</var>) * <var class=”var”>sar</var>. </dd> <dt><samp class=”option”>hsub, vsub</samp></dt> <dd> Horizontal and vertical chroma subsample values. For example, for the pixel format "yuv422p" <var class=”var”>hsub</var> is 2 and <var class=”var”>vsub</var> is 1. </dd> </dl>

 <h4 class=”subsection”>39.228.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> To change the display aspect ratio to 16:9, specify one of the following: <pre class=”example-preformatted”>setdar=dar=1.77777 setdar=dar=16/9 </pre>

To change the sample aspect ratio to 10:11, specify: <pre class=”example-preformatted”>setsar=sar=10/11 </pre>

To set a display aspect ratio of 16:9, and specify a maximum integer value of 1000 in the aspect ratio reduction, use the command: <pre class=”example-preformatted”>setdar=ratio=16/9:max=1000 </pre>

 <h3 class=”section”>39.229 setfield# TOC</h3>

Force field for the output video frame. The <code class=”code”>setfield</code> filter marks the interlace type field for the output frames. It does not change the input frame, but only sets the corresponding property, which affects how the frame is treated by following filters (e.g. <code class=”code”>fieldorder</code> or <code class=”code”>yadif</code>). The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>mode</samp></dt> <dd> Available values are: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Keep the same field property. </dd> <dt>‘<samp class=”samp”>bff</samp>’</dt> <dd> Mark the frame as bottom-field-first. </dd> <dt>‘<samp class=”samp”>tff</samp>’</dt> <dd> Mark the frame as top-field-first. </dd> <dt>‘<samp class=”samp”>prog</samp>’</dt> <dd> Mark the frame as progressive. </dd> </dl> </dd> </dl>

 <h3 class=”section”>39.230 setparams# TOC</h3>

Force frame parameter for the output video frame. The <code class=”code”>setparams</code> filter marks interlace and color range for the output frames.  <h4 class="subsection">39.241.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">39.242 spp# TOC</h3>

Apply a simple postprocessing filter that compresses and decompresses the image at several (or - in the case of <samp class="option">quality</samp> level <code class="code">6</code> - all) shifts and average the results. The filter accepts the following options: <dl class="table"> <dt><samp class="option">quality</samp></dt> <dd> Set quality. This option defines the number of levels for averaging. It accepts an integer in the range 0-6. If set to <code class="code">0</code>, the filter will have no effect. A value of <code class="code">6</code> means the higher quality. For each increment of that value the speed drops by a factor of approximately 2. Default value is <code class="code">3</code>. </dd> <dt><samp class="option">qp</samp></dt> <dd> Force a constant quantization parameter. If not set, the filter will use the QP from the video stream (if available). </dd> <dt><samp class="option">mode</samp></dt> <dd> Set thresholding mode. Available modes are: <dl class="table"> <dt>‘<samp class="samp">hard</samp>’</dt> <dd> Set hard thresholding (default). </dd> <dt>‘<samp class="samp">soft</samp>’</dt> <dd> Set soft thresholding (better de-ringing effect, but likely blurrier). </dd> </dl>

</dd> <dt><samp class="option">use_bframe_qp</samp></dt> <dd> Enable the use of the QP from the B-Frames if set to <code class="code">1</code>. Using this option may cause flicker since the B-Frames have often larger QP. Default is <code class="code">0</code> (not enabled). </dd> </dl>

 <h4 class="subsection">39.242.1 Commands# TOC</h4>

This filter supports the following commands: <dl class="table"> <dt><samp class="option">quality, level</samp></dt> <dd> Set quality level. The value <code class="code">max</code> can be used to set the maximum level, currently <code class="code">6</code>. </dd> </dl>

 <h3 class="section">39.243 sr# TOC</h3>

Scale the input by applying one of the super-resolution methods based on convolutional neural networks. Supported models: <ul class="itemize mark-bullet"> Super-Resolution Convolutional Neural Network model (SRCNN). See https://arxiv.org/abs/1501.00092.

Efficient Sub-Pixel Convolutional Neural Network model (ESPCN). See https://arxiv.org/abs/1609.05158.

Training scripts as well as scripts for model file (.pb) saving can be found at <a class="url" href="https://github.com/XueweiMeng/sr/tree/sr_dnn_native">https://github.com/Xuewei Original repository is at <a class="url" href="https://github.com/HighVoltageRocknRoll/sr.git">https://gith The filter accepts the following options: <dl class="table"> <dt><samp class="option">dnn_backend</samp></dt> <dd> Specify which DNN backend to use for model loading and execution. This option accepts the following values: <dl class="table"> <dt>‘<samp class="samp">tensorflow</samp>’</dt> <dd> TensorFlow backend. To enable this backend you need to install the TensorFlow for C library (see <a class="url" href="https://www.tensorflow.org/install/lang_c">https://www.tensorflow.org/install/lang_ and configure FFmpeg with <code class="code">--enable-libtensorflow</code> </dd> </dl>

</dd> <dt><samp class="option">model</samp></dt> <dd> Set path to model file specifying network architecture and its parameters. Note that different backends use different file formats. TensorFlow, OpenVINO backend can load files for only its format. </dd> <dt><samp class="option">scale_factor</samp></dt> <dd> Set scale factor for

SRCNN model. Allowed values are <code class=”code”>2</code>, <code class=”code”>3</code> and <code class=”code”>4</code>. Default value is <code class=”code”>2</code>. Scale factor is necessary for SRCNN model, because it accepts input upscaled using bicubic upscaling with proper scale factor. </dd> </dl>

To get full functionality (such as async execution), please use the dnn_processing filter. <h3 class=”section”>39.244 sr_amf# TOC</h3>

Upscale (size increasing) for the input video using AMD Advanced Media Framework library for hardware acceleration. Use advanced algorithms for upscaling with higher output quality. Setting the output width and height works in the same way as for the scale filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>w</samp></dt> <dt><samp class=”option”>h</samp></dt> <dd> Set the output video dimension expression. Default value is the input dimension. Allows for the same expressions as the scale filter. </dd> <dt><samp class=”option”>algorithm</samp></dt> <dd> Sets the algorithm used for scaling: <dl class=”table”> <dt><var class=”var”>bilinear</var></dt> <dd> Bilinear </dd> <dt><var class=”var”>bicubic</var></dt> <dd> Bicubic </dd> <dt><var class=”var”>sr1-0</var></dt> <dd> Video SR1.0 This is a default value </dd> <dt><var class=”var”>point</var></dt> <dd> Point AMF returns an unwritten surface for this algorithm when the format is <code class=”code”>nv12</code> or <code class=”code”>p010</code>, so inputs in those formats are converted to a packed RGB format automatically. This is a driver bug rather than a documented restriction; the conversion can be dropped once a driver that scales <code class=”code”>nv12</code> and <code class=”code”>p010</code> correctly with <code class=”code”>point</code> is in wide use. </dd> <dt><var class=”var”>sr1-1</var></dt> <dd> Video SR1.1 This algorithm only supports packed RGB formats and requires a DirectX 11 or DirectX 12 device, so it is available on Windows only. Inputs in other formats such as <code class=”code”>nv12</code> or <code class=”code”>p010</code> are converted to a packed RGB format automatically. Note that the VideoSR algorithms (<code class=”code”>sr1-0</code> and <code class=”code”>sr1-1</code>) do not preserve the alpha channel (it is left zeroed); drop it after the download, e.g. with <code class=”code”>hwdownload,format=rgba,format=rgb24</code>, if an opaque result is required. </dd> </dl>

</dd> <dt><samp class=”option”>sharpness</samp></dt> <dd> Control

hq scaler sharpening. The value is a float in the range of [0.0, 2.0] </dd> <dt><samp class="option">format</samp></dt> <dd> Controls the output pixel format. By default, or if none is specified, the input pixel format is used. The <code class="code">point</code> and <code class="code">sr1-1</code> algorithms emit the packed RGB format the scaler receives, so for them this option must name one of <code class="code">rgba</code>, <code class="code">bgra</code>, <code class="code">x2bgr10le</code> or <code class="code">rgbaf16le</code>. A named format also decides what software input is converted to, and what a hardware surface in another format is converted to on the GPU. Without it, <code class="code">x2bgr10le</code> is selected for <code class="code">p010</code> input and <code class="code">rgba</code> for other non-RGB input, and the result is tagged as full range RGB. libswscale cannot convert other software formats to <code class="code">rgbaf16le</code>; use software input already in that format or a hardware input for GPU conversion. </dd> <dt><samp class="option">keep-ratio</samp></dt> <dd> Force the scaler to keep the aspect ratio of the input image when the output size has a different aspect ratio. Default value is false. </dd> <dt><samp class="option">fill</samp></dt> <dd> Specifies whether the output image outside the region of interest, which does not fill the entire output surface should be filled with a solid color. </dd> </dl>

 <h3 class="section">39.245 ssim#
TOC</h3>

Obtain the SSIM (Structural SImilarity Metric) between two input videos. This filter takes in input two input videos, the first input is considered the "main" source and is passed unchanged to the output. The second input is used as a "reference" video for computing the SSIM. Both video inputs must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have

the same number of frames, which are compared one by one. The filter stores the calculated SSIM of each frame. The description of the accepted parameters follows. <dl class="table"> <dt><samp class="option">stats_file, f</samp></dt> <dd> If specified the filter will use the named file to save the SSIM of each individual frame. When filename equals "-" the data is sent to standard output. </dd> </dl>

The file printed if <var class="var">stats_file</var> is selected, contains a sequence of key/value pairs of the form <var class="var">key</var>:<var class="var">value</var> for each compared couple of frames. A description of each shown parameter follows: <dl class="table"> <dt><samp class="option">n</samp></dt> <dd> sequential number of the input frame, starting from 1 </dd> <dt><samp class="option">Y, U, V, R, G, B</samp></dt> <dd> SSIM of the compared frames for the component specified by the suffix. </dd> <dt><samp class="option">All</samp></dt> <dd> SSIM of the compared frames for the whole frame. </dd> <dt><samp class="option">dB</samp></dt> <dd> Same as above but in dB representation. </dd> </dl>

This filter also supports the framesync options. <h4 class="subsection">39.245.1 Examples# TOC</h4> <ul class="itemize mark-bullet"> For example: <pre class="example-preformatted">movie=ref_movie.mpg, setpts=PTS-STARTPTS [main]; [main][ref] ssim="stats_file=stats.log" [out] </pre>

On this example the input file being processed is compared with the reference file <samp class="file">ref_movie.mpg</samp>. The SSIM of each individual frame is stored in <samp class="file">stats.log</samp>. Another example with both psnr and ssim at same time: <pre class="example-preformatted">ffmpeg -i main.mpg -i ref.mpg -lavfi "ssim;[0:v][1:v]psnr" -f null - </pre>

Another example with different containers: <pre class="example-preformatted">ffmpeg -i main.mpg -i ref.mkv -lavfi "[0:v]settb=AVTB,setpts=PTS-STARTPTS[main];[1:v]settb=AVTB,setpts=PTS-STARTPTS[ref];[main][ref]ssim" -f null - </pre>

 <h3 class=”section”>39.258 tiltandshift# TOC</h3> Apply tilt-and-shift effect. What happens when you invert time and space? Normally a video is composed of several frames that represent a different instant of time and shows a scene that evolves in the space captured by the frame. This filter is the antipode of that concept, taking inspiration from tilt and shift photography. A filtered frame contains the whole timeline of events composing the sequence, and this is obtained by placing a slice of pixels from each frame into a single one. However, since there are no infinite-width frames, this is done up the width of the input frame, and a video is recomposed by shifting away one column for each subsequent frame. In order to map space to time, the filter tilts each input frame as well, so that motion is preserved. This is accomplished by progressively selecting a different column from each input frame. The end result is a sort of inverted parallax, so that far away objects move much faster that the ones in the front. The ideal conditions for this video effect are when there is either very little motion and the background is static, or when there is a lot of motion and a very wide depth of field (e.g. wide panorama, while moving on a train). The filter accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>tilt</samp></dt> <dd> Tilt video while shifting (default). When unset, video will be sliding a static image, composed of the first column of each frame. </dd> <dt><samp class=”option”>start</samp></dt> <dd> What to do at the start of filtering (see below). </dd> <dt><samp class=”option”>end</samp></dt> <dd> What to do at the end of filtering (see below). </dd> <dt><samp class=”option”>hold</samp></dt> <dd> How many columns should pass through before start of filtering. </dd> <dt><samp class=”option”>pad</samp></dt> <dd> How many columns should be inserted before end of filtering. </dd> </dl>

Normally the filter shifts and tilts from the very first frame, and stops when the last one is received. However, before filtering starts, normal video may be preserved, so that the effect is slowly shifted in its place. Similarly, the last video frame may be reconstructed at the end. Alternatively it is possible to just start and end with black. <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> Filtering starts immediately and ends when the last frame is received. </dd> <dt>‘<samp class=”samp”>frame</samp>’</dt> <dd> The first frames or the very last frame are kept intact during processing.

</dd> <dt>‘<samp class="samp">black</samp>’</dt> <dd> Black is padded at the beginning or at the end of filtering. </dd> </dl>

 <h3 class="section">39.259 tinterlace# TOC</h3>

This filter supports the following commands: <dl class="table"> <dt><samp class="option">weights</samp></dt> <dt><samp class="option">scale</samp></dt> <dt><samp class="option">planes</samp></dt> <dd> Syntax is same as option with same name. </dd> </dl>

 <h3 class="section">39.263 tonemap# TOC</h3> Tone map colors from different dynamic ranges. This filter expects data in single precision floating point, as it needs to operate on (and can output) out-of-range values. Another filter, such as zscale, is needed to convert the resulting frame to a usable format. The tonemapping algorithms implemented only work on linear light, so input data should be linearized beforehand (and possibly correctly tagged).   <pre class="example-preformatted">ffmpeg -i INPUT -vf zscale=transfer=linear,tonemap=clip,zscale=transfer=bt709,format=yuv420p OUTPUT </pre>

 <h4 class="subsection">39.263.1 Options# TOC</h4> The filter accepts the following options. <dl class="table"> <dt><samp class="option">tonemap</samp></dt> <dd> Set the tone map algorithm to use. Possible values are: <dl class="table"> <dt><var class="var">none</var></dt> <dd> Do not apply any tone map, only desaturate overbright pixels. </dd> <dt><var class="var">clip</var></dt> <dd> Hard-clip any out-of-range values. Use it for perfect color accuracy for in-range values, while distorting out-of-range values. </dd> <dt><var class="var">linear</var></dt>

<dd> Stretch the entire reference gamut to a linear multiple of the display. </dd> <dt><var class="var">gamma</var></dt> <dd> Fit a logarithmic transfer between the tone curves. </dd> <dt><var class="var">reinhard</var></dt> <dd> Preserve overall image brightness with a simple curve, using nonlinear contrast, which results in flattening details and degrading color accuracy. </dd> <dt><var class="var">hable</var></dt> <dd> Preserve both dark and bright details better than <var class="var">reinhard</var>, at the cost of slightly darkening everything. Use it when detail preservation is more important than color and brightness accuracy. </dd> <dt><var class="var">mobius</var></dt> <dd> Smoothly map out-of-range values, while retaining contrast and colors for in-range material as much as possible. Use it when color accuracy is more important than detail preservation. </dd> </dl>

Default is none. </dd> <dt><samp class="option">param</samp></dt> <dd> Tune the tone mapping algorithm. This affects the following algorithms: <dl class="table"> <dt><var class="var">none</var></dt> <dd> Ignored. </dd> <dt><var class="var">linear</var></dt> <dd> Specifies the scale factor to use while stretching. Default to 1.0. </dd> <dt><var class="var">gamma</var></dt> <dd> Specifies the exponent of the function. Default to 1.8. </dd> <dt><var class="var">clip</var></dt> <dd> Specify an extra linear coefficient to multiply into the signal before clipping. Default to 1.0. </dd> <dt><var class="var">reinhard</var></dt> <dd> Specify the local contrast coefficient at the display peak. Default to 0.5, which means that in-gamut values will be about half as bright as when clipping. </dd> <dt><var class="var">hable</var></dt> <dd> Ignored. </dd> <dt><var class="var">mobius</var></dt> <dd> Specify the transition point from linear to mobius transform. Every value below this point is guaranteed to be mapped 1:1. The higher the value, the more accurate the result will be, at the cost of losing bright details. Default to 0.3, which due to the steep initial slope still preserves in-range colors fairly accurately. </dd> </dl>

</dd> <dt><samp class="option">desat</samp></dt> <dd> Apply desaturation for highlights that exceed this level of brightness. The higher the parameter, the more color information will be preserved. This setting helps prevent unnaturally blown-out colors for super-highlights, by (smoothly) turning into white instead. This makes images feel more natural, at the cost of reducing information about out-of-range colors. The default of 2.0 is somewhat conservative and will mostly just apply to skies or directly sunlit surfaces. A setting of 0.0 disables this option. This option works only if the input frame has a supported color tag. </dd> <dt><samp class="option">peak</samp></dt> <dd> Override signal/nominal/reference peak with this value. Useful when the embedded peak information in display metadata is not reliable or when tone mapping from a

lower range to a higher range. </dd> </dl>

 <h3 class="section">39.264 tpad#
TOC</h3>

Temporarily pad video frames. The filter accepts the following options: <dl class="table"> <dt><samp class="option">start</samp></dt>

It accepts the following values: <dl class="table">
<dt>‘<samp class="samp">none</samp>’</dt> <dd> Always
apply transposition. </dd> <dt>‘<samp class="samp">portrait</samp>’</dt>
<dd> Preserve portrait geometry (when <var class="var">height</var>
>= <var class="var">width</var>). </dd> <dt>‘<samp
class="samp">landscape</samp>’</dt> <dd> Preserve
landscape geometry (when <var class="var">width</var> >= <var
class="var">height</var>). </dd> </dl>

Default value is <code class="code">none</code>. </dd> </dl>

For example to rotate by 90 degrees clockwise and preserve portrait layout:
 <pre class="example-preformatted">transpose=dir=1:passthrough=portrait
</pre>

The command above can also be specified as:
<pre class="example-preformatted">transpose=1:portrait </pre>

 <h3 class="section">39.266 trim<span class="pull-
right">#
TOC</h3>
Trim the input so that the output contains one continuous subpart of the input. It accepts the following parameters: <dl class="table">
<dt><samp class="option">start</samp></dt> <dd> Specify the
time of the start of the kept section, i.e. the frame with the timestamp <var class="var">start</var> will be the first frame in the output. </dd> <dt><samp class="option">end</samp></dt>
<dd> Specify the time of the first frame that will be dropped,

i.e. the frame immediately preceding the one with the timestamp <var class=”var”>end</var> will be the last frame in the output. </dd> <dt><samp class=”option”>start_pts</samp></dt> <dd> This is the same as <var class=”var”>start</var>, except this option sets the start timestamp in timebase units instead of seconds. </dd> <dt><samp class=”option”>end_pts</samp></dt> <dd> This is the same as <var class=”var”>end</var>, except this option sets the end timestamp in timebase units instead of seconds. </dd> <dt><samp class=”option”>duration</samp></dt> <dd> The maximum duration of the output in seconds. </dd> <dt><samp class=”option”>start_frame</samp></dt> <dd> The number of the first frame that should be passed to the output. </dd> <dt><samp class=”option”>end_frame</samp></dt> <dd> The number of the first frame that should be dropped. </dd> </dl>

<samp class=”option”>start</samp>, <samp class=”option”>end</samp>, and <samp class=”option”>duration</samp> are expressed as time duration specifications; see <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#time-duration-syntax”>the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. Note that the first two sets of the start/end options and the <samp class=”option”>duration</samp> option look at the frame timestamp, while the _frame variants simply count the frames that pass through the filter. Also note that this filter does not modify the timestamps. If you wish for the output timestamps to start at zero, insert a setpts filter after the trim filter. If multiple start or end options are set, this filter tries to be greedy and keep all the frames that match at least one of the specified constraints. To keep only the part that matches all the constraints at once, chain multiple trim filters. The defaults are such that all the input is kept. So it is possible to set e.g. just the end values to keep everything before the specified time. Examples: <ul class=”itemize mark-bullet”> Drop everything except the second minute of input: <pre class=”example-preformatted”>ffmpeg -i INPUT -vf trim=60:120 </pre>

Keep only the first second: <pre class=”example-preformatted”>ffmpeg -i INPUT -vf trim=duration=1 </pre>

 <h3 class=”section”>39.267 unpremultiply# TOC</h3> Apply alpha unpremultiply effect to input video stream using first plane of second stream as alpha. Both streams must have same dimensions and same pixel format. The filter accepts the following option: <dl class=”table”> <dt><samp class=”option”>planes</samp></dt>

<dd> Set which planes will be processed, unprocessed planes will be copied. By default value 0xf, all planes will be processed. If the format has 1 or 2 components, then luma is bit 0. If the format has 3 or 4 components: for RGB formats bit 0 is green, bit 1 is blue and bit 2 is red; for YUV formats bit 0 is luma, bit 1 is chroma-U and bit 2 is chroma-V. If present, the alpha channel is always the last bit. </dd> <dt><samp class="option">inplace</samp></dt> <dd> Do not require 2nd input for processing, instead use alpha plane from input stream. </dd> </dl>

 <h3 class="section">39.268 unsharp# TOC</h3>

Sharpen or blur the input video. It accepts the following parameters: <dl class="table"> <dt><samp class="option">luma_msize_x, lx</samp></dt> <dd> Set the luma matrix horizontal size. <ul class="itemize mark-bullet"> Use <code class="command">ffmpeg</code> for a typical stabilization with default values:
<pre class="example-preformatted">ffmpeg -i inp.mpeg -vf vidstabtransform,unsharp=5:5:0.8:3:3:0.4 inp_stabilized.mpeg </pre>

Note the use of the unsharp filter which is always recommended. Zoom in a bit more and load transform data from a given file: <pre class="example-preformatted">vidstabtransform=zoom=5:input="mytransforms.trf"
</pre>

Smoothen the video even more: <pre class="example-preformatted">vidstabtransform=smoothing=30 </pre>

 <h3 class="section">39.277 vflip#
TOC</h3>

Flip the input video vertically. For example, to vertically

flip a video with <code class=”command”>ffmpeg</code>: <pre class=”example-preformatted”>ffmpeg -i in.avi -vf "vflip" out.avi </pre>

 <h3 class=”section”>39.278 vfrdet# TOC</h3>

Detect variable frame rate video. This filter tries to detect if the input is variable or constant frame rate. At end it will output number of frames detected as having variable delta pts, and ones with constant delta pts. If there was frames with variable delta, than it will also show min, max and average delta encountered. <h3 class=”section”>39.279 vibrance# TOC</h3>

Boost or alter saturation. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>intensity</samp></dt> <dd> Set strength of boost if positive value or strength of alter if negative value. Default is 0. Allowed range is from -2 to 2. </dd> <dt><samp class=”option”>rbal</samp></dt> <dd> Set the red balance. Default is 1. Allowed range is from -10 to 10. </dd> <dt><samp class=”option”>gbal</samp></dt> <dd> Set the green balance. Default is 1. Allowed range is from -10 to 10. </dd> <dt><samp class=”option”>bbal</samp></dt> <dd> Set the blue balance. Default is 1. Allowed range is from -10 to 10. </dd> <dt><samp class=”option”>rlum</samp></dt> <dd> Set the red luma coefficient. </dd> <dt><samp class=”option”>glum</samp></dt> <dd> Set the green luma coefficient. </dd> <dt><samp class=”option”>blum</samp></dt> <dd> Set the blue luma coefficient. </dd> <dt><samp class=”option”>alternate</samp></dt> <dd> If <code class=”code”>intensity</code> is negative and this is set to 1, colors will change, otherwise colors will be less saturated, more towards gray. </dd> </dl>

 <h4 class=”subsection”>39.279.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class=”section”>39.280 vif# TOC</h3>

Obtain the average VIF (Visual Information Fidelity) between two input

videos. This filter takes two input videos. Both input videos must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained average VIF score is printed through the logging system. The filter stores the calculated VIF score of each frame. This filter also supports the framesync options. In the below example the input file <samp class=”file”>main.mpg</samp> being processed is compared with the reference file <samp class=”file”>ref.mpg</samp>.   <pre class=”example-preformatted”>ffmpeg -i main.mpg -i ref.mpg -lavfi vif -f null - </pre>

 <h3 class=”section”>39.281 vignette# TOC</h3>

Make or reverse a natural vignetting effect. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>angle, a</samp></dt> <dd> Set lens angle expression as a number of radians. The value is clipped in the <code class=”code”>[0,PI/2]</code> range. Default value: <code class=”code”>"PI/5"</code> </dd> <dt><samp class=”option”>x0</samp></dt> <dt><samp class=”option”>y0</samp></dt> <dd> Set center coordinates expressions. Respectively <code class=”code”>"w/2"</code> and <code class=”code”>"h/2"</code> by default. </dd> <dt><samp class=”option”>mode</samp></dt> <dd> Set forward/backward mode. Available modes are: <dl class=”table”> <dt>‘<samp class=”samp”>forward</samp>’</dt> <dd> The larger the distance from the central point, the darker the image becomes. </dd> <dt>‘<samp class=”samp”>backward</samp>’</dt> <dd> The larger the distance from the central point, the brighter the image becomes. This can be used to reverse a vignette effect, though there is no automatic detection to extract the lens <samp class=”option”>angle</samp> and other settings (yet). It can also be used to create a burning effect. </dd> </dl>

Default value is ‘<samp class=”samp”>forward</samp>’. </dd> <dt><samp class=”option”>eval</samp></dt> <dd> Set evaluation mode for the expressions (<samp class=”option”>angle</samp>, <samp class=”option”>x0</samp>, <samp class=”option”>y0</samp>). It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>init</samp>’</dt> <dd> Evaluate expressions only once during the filter initialization. </dd> <dt>‘<samp class=”samp”>frame</samp>’</dt> <dd> Evaluate expressions for each incoming frame. This is way slower than the ‘<samp class=”samp”>init</samp>’ mode since it requires all the scalers to

be re-computed, but it allows advanced dynamic expressions. </dd>
</dl>

Default value is ‘<samp class="samp">init</samp>’.
 </dd> <dt><samp class="option">dither</samp></dt> <dd> Set
dithering to reduce the circular banding effects. Default is <code
class="code">1</code> (enabled). </dd> <dt><samp class="option">aspect</samp></dt>
<dd> Set vignette aspect. This setting allows one to adjust the shape of
the vignette. Setting this value to the SAR of the input will make a rectangular
vignetting following the dimensions of the video. Default is <code
class="code">1/1</code>. </dd> </dl>

 <h4 class=”subsection”>39.283.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Scale input to 720p, keeping aspect ratio and ensuring the output is yuv420p. The filter always outputs AMF surfaces, so a hwdownload is needed to feed a software encoder. <pre class=”example-preformatted”>vpp_amf=-2:720:format=yuv420p,hwdownload,format=yuv420p </pre>

Upscale to 4K and change color profile to bt2020. <pre class=”example-preformatted”>vpp_amf=4096:2160:color_profile=bt2020 </pre>

Override input primaries and input transfer characteristics, change both to bt709.

 <pre class=”example-preformatted”>vpp_amf=color_profile=bt2020:in_trc=smpte2 </pre>

 <h3 class=”section”>39.284 vstack# TOC</h3> Stack input videos vertically. All streams must be of same pixel format and of same width. Note that this filter is faster than using overlay and pad filter to create same output. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>inputs</samp></dt> <dd> Set number of input streams. Default is 2. </dd> <dt><samp class=”option”>shortest</samp></dt> <dd> If set to 1, force the output to terminate when the shortest input terminates. Default value is 0. </dd> </dl>

 <h3 class=”section”>39.285 w3fdif<a class=”anchor hidden-xs” href=”#w3fdif” aria-

hidden=”true”># TOC</h3>

Deinterlace the input video ("w3fdif" stands for "Weston 3 Field Deinterlacing Filter"). Based on the process described by Martin Weston for BBC R&D, and implemented based on the de-interlace algorithm written by Jim Easterbrook for BBC R&D, the Weston 3 field deinterlacing filter uses filter coefficients calculated by BBC R&D. This filter uses field-dominance information in frame to decide which of each pair of fields to place first in the output. If it gets it wrong use setfield filter before <code class=”code”>w3fdif</code> filter. There are two sets of filter coefficients, so called "simple" and "complex". Which set of filter coefficients is used can be set by passing an optional parameter: <dl class=”table”> <dt><samp class=”option”>filter</samp></dt> <dd> Set the interlacing filter coefficients. Accepts one of the following values: <dl class=”table”> <dt>‘<samp class=”samp”>simple</samp>’</dt> <dd> Simple filter coefficient set. </dd> <dt>‘<samp class=”samp”>complex</samp>’</dt> <dd> More-complex filter coefficient set. </dd> </dl> Default value is ‘<samp class=”samp”>complex</samp>’. </dd> <dt><samp class=”option”>mode</samp></dt> <dd> The interlacing mode to adopt. It accepts one of the following values: <dl class=”table”> <dt><samp class=”option”>frame</samp></dt> <dd> Output one frame for each frame. </dd> <dt><samp class=”option”>field</samp></dt> <dd> Output one frame for each field. </dd> </dl>

The default value is <code class=”code”>field</code>. </dd> <dt><samp class=”option”>parity</samp></dt> <dd> The picture field parity assumed for the input interlaced video. It accepts one of the following values: <dl class=”table”> <dt><samp class=”option”>tff</samp></dt> <dd> Assume the top field is first. </dd> <dt><samp class=”option”>bff</samp></dt> <dd> Assume the bottom field is first. </dd> <dt><samp class=”option”>auto</samp></dt> <dd> Enable automatic detection of field parity. </dd> </dl>

The default value is <code class=”code”>auto</code>. If the interlacing is unknown or the decoder does not export this information, top field first will be assumed. </dd> <dt><samp class=”option”>deint</samp></dt> <dd> Specify which frames to deinterlace. Accepts one of the following values: <dl class=”table”> <dt>‘<samp class=”samp”>all</samp>’</dt> <dd> Deinterlace all frames, </dd> <dt>‘<samp class=”samp”>interlaced</samp>&rsquo <dd> Only deinterlace frames marked as interlaced. </dd> </dl>

Default value is ‘<samp class=”samp”>all</samp>’. </dd> </dl>

 <h4 class="subsection">39.285.1 Commands# TOC</h4> This filter supports same commands as options. <h3 class="section">39.286 waveform# TOC</h3> Video waveform monitor. The waveform monitor plots color component intensity. By default luma only. Each column of the waveform corresponds to a column of pixels in the source video. It accepts the following options: <dl class="table"> <dt><samp class="option">mode, m</samp></dt> <dd> Can be either <code class="code">row</code>, or <code class="code">column</code>. Default is <code class="code">column</code>. In row mode, the graph on the left side represents color component value 0 and the right side represents value = 255. In column mode, the top side represents color component value = 0 and bottom side represents value = 255. </dd> <dt><samp class="option">intensity, i</samp></dt> <dd> Set intensity. Smaller values are useful to find out how many values of the same luminance are distributed across input rows/columns. Default value is <code class="code">0.04</code>. Allowed range is [0, 1]. </dd> <dt><samp class="option">mirror, r</samp></dt> <dd> Set mirroring mode. <code class="code">0</code> means unmirrored, <code class="code">1</code> means mirrored. In mirrored mode, higher values will be represented on the left side for <code class="code">row</code> mode and at the top for <code class="code">column</code> mode. Default is <code class="code">1</code> (mirrored). </dd> <dt><samp class="option">display, d</samp></dt> <dd> Set display mode. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">overlay</samp>’</dt> <dd> Presents information identical to that in the <code class="code">parade</code>, except that the graphs representing color components are superimposed directly over one another. This display mode makes it easier to spot relative differences or similarities in overlapping areas of the color components that are supposed to be identical, such as neutral whites, grays, or blacks. </dd> <dt>‘<samp class="samp">stack</samp>’</dt> <dd> Display separate graph for the color components side by side in <code class="code">row</code> mode or one below the other in <code class="code">column</code> mode. </dd> <dt>‘<samp class="samp">parade</samp>’</dt> <dd> Display separate graph for the color components side by side in <code class="code">column</code> mode or one below the other in <code class="code">row</code> mode. Using this display mode makes it easy to spot color casts in the highlights and shadows of an image, by comparing the contours of the top and the bottom

graphs of each waveform. Since whites, grays, and blacks are characterized by exactly equal amounts of red, green, and blue, neutral areas of the picture should display three waveforms of roughly equal width/height. If not, the correction is easy to perform by making level adjustments the three waveforms. </dd> </dl> Default is <code class="code">stack</code>. </dd> <dt><samp class="option">components, c</samp></dt> <dd> Set which color components to display. Default is 1, which means only luma or red color component if input is in RGB colorspace.  <h4 class="subsection">39.291.1 Commands# TOC</h4>

This filter supports all above options as commands, excluding option <code class="code">inputs</code>. <h3 class="section">39.292 xpsnr# TOC</h3>

Obtain the average (across all input frames) and minimum (across all color plane averages) eXtended Perceptually weighted peak Signal-to-Noise Ratio (XPSNR) between two input videos. The XPSNR is a low-complexity psychovisually motivated distortion measurement algorithm for assessing the difference between two video streams or images. This is especially useful for objectively quantifying the distortions caused by video and image codecs, as an alternative to a formal subjective test. The logarithmic XPSNR output values are in a similar range as those of traditional psnr assessments but better reflect human impressions of visual coding quality. More details on the XPSNR measure, which essentially represents a blockwise weighted variant of the PSNR measure, can be found in the following freely available papers: <ul class="itemize mark-bullet"> C. R. Helmrich, M. Siekmann, S. Becker, S. Bosse, D. Marpe, and T. Wiegand, "XPSNR: A Low-Complexity Extension of the Perceptually Weighted Peak Signal-to-Noise Ratio for High-Resolution Video Quality Assessment," in Proc. IEEE Int. Conf. Acoustics, Speech, Sig. Process. (ICASSP), virt./online, May 2020. www.ecodis.de/xpsnr.htm

C. R. Helmrich, S. Bosse, H. Schwarz, D. Marpe, and T. Wiegand, "A Study of the Extended Perceptually Weighted Peak Signal-to-Noise Ratio (XPSNR) for Video Compression with Different Resolutions and Bit Depths," ITU Journal: ICT Discoveries, vol. 3, no. 1, pp. 65 - 72, May 2020. http://handle.itu.int/11.1002/pub/8153d78b-en

When publishing the results of XPSNR assessments obtained using, e.g., this FFmpeg filter, a reference to the above papers as a means of documentation is strongly encouraged. The filter requires two input videos. The first input is considered a (usually not distorted) reference source and is passed unchanged to the output, whereas the second input is a (distorted) test sig-

nal. Except for the bit depth, these two video inputs must have the same pixel format. In addition, for best performance, both compared input videos should be in YCbCr color format. The obtained overall XPSNR values mentioned above are printed through the logging system. In case of input with multiple color planes, we suggest reporting of the minimum XPSNR average. The following parameter, which behaves like the one for the psnr filter, is accepted: <dl class="table"> <dt><samp class="option">stats_file, f</samp></dt> <dd> If specified, the filter will use the named file to save the XPSNR value of each individual frame and color plane. When the file name equals "-", that data is sent to standard output. </dd> </dl>

This filter also supports the framesync options. <h4 class="subsection">39.292.1 Examples# TOC</h4> <ul class="itemize mark-bullet"> XPSNR analysis of two 1080p HD videos, ref_source.yuv and test_video.yuv, both at 24 frames per second, with color format 4:2:0, bit depth 8, and output of a logfile named "xpsnr.log": <pre class="example-preformatted">ffmpeg -s 1920x1080 -framerate 24 -pix_fmt yuv420p -i ref_source.yuv -s 1920x1080 -framerate 24 -pix_fmt yuv420p -i test_video.yuv -lavfi xpsnr="stats_file=xpsnr.log" -f null - </pre>

 <h3 class="section">39.293 xstack# TOC</h3> Stack video inputs into custom layout. All streams must be of same pixel format. The filter accepts the following options: <dl class="table"> <dt><samp class="option">inputs</samp></dt> <dd> Set number of input streams. Default is 2. </dd> <dt><samp class="option">layout</samp></dt> <dd> Specify layout of inputs. This option requires the desired layout configuration to be explicitly set by the user. This sets position of each video input in output. Each input is separated by ’|’. The first number represents the column, and the second number represents the row. Numbers start at 0 and are separated by ’_’. Optionally one can use wX and hX, where

X is video input from which to take width or height. Multiple values can be used when separated by ’+’. In such case values are summed together. Note that if inputs are of different sizes gaps may appear, as not all of the output video frame will be filled. Similarly, videos can overlap each other if their position doesn’t leave enough space for the full frame of adjoining videos. For 2 inputs, a default layout of <code class="code">0_0|w0_0</code> (equivalent to <code class="code">grid=2x1</code>) is set. In all other cases, a layout or a grid must be set by the user. Either <code class="code">grid</code> or <code class="code">layout</code> can be specified at a time. Specifying both will result in an error. </dd> <dt><samp class="option">grid</samp></dt> <dd> Specify a fixed size grid of inputs. This option is used to create a fixed size grid of the input streams. Set the grid size in the form <code class="code">COLUMNSxROWS</code>. There must be <code class="code">ROWS * COLUMNS</code> input streams and they will be arranged as a grid with <code class="code">ROWS</code> rows and <code class="code">COLUMNS</code> columns. When using this option, each input stream within a row must have the same height and all the rows must have the same width. If <code class="code">grid</code> is set, then <code class="code">inputs</code> option is ignored and is implicitly set to <code class="code">ROWS * COLUMNS</code>. For 2 inputs, a default grid of <code class="code">2x1</code> (equivalent to <code class="code">layout=0_0|w0_0</code>) is set. In all other cases, a layout or a grid must be set by the user. Either <code class="code">grid</code> or <code class="code">layout</code> can be specified at a time. Specifying both will result in an error. </dd> <dt><samp class="option">shortest</samp></dt> <dd> If set to 1, force the output to terminate when the shortest input terminates. Default value is 0. </dd> <dt><samp class="option">fill</samp></dt> <dd> If set to valid color, all unused pixels will be filled with that color. By default fill is set to none, so it is disabled. </dd> </dl>

Zoom in 2x into center of picture only for the first second of the input video: <pre class=”example-preformatted”>zoompan=z='if(between(in_time,0,1),2,1)':d=1:x='iw/2-
(iw/zoom/2)':y='ih/2-(ih/zoom/2)' </pre>

 <h3 class=”section”>39.297 zscale# TOC</h3>
Scale (resize) the input video, using the z.lib library: https://github.com/sekrit-twc/zimg. To enable compilation of this filter, you need to configure FFmpeg with <code class=”code”>--enable-libzimg</code>. The zscale filter forces the output display aspect ratio to be the same as the input, by changing the output sample aspect ratio. If the input image format is different from the format requested by the next filter, the zscale filter will convert the input to the requested format. <h4 class=”subsection”>39.297.1 Options# TOC</h4> The filter accepts the following options. <dl class=”table”> <dt><samp class=”option”>width, w</samp></dt> <dt><samp class=”option”>height, h</samp></dt> <dd> Set the output video dimension expression. Default value is the input dimension. If the <var class=”var”>width</var> or <var class=”var”>w</var> value is 0, the

input width is used for the output. If the <var class=”var”>height</var> or <var class=”var”>h</var> value is 0, the input height is used for the output. If one and only one of the values is -n with n >= 1, the zscale filter will use a value that maintains the aspect ratio of the input image, calculated from the other specified dimension. After that it will, however, make sure that the calculated dimension is divisible by n and adjust the value if necessary. If both values are -n with n >= 1, the behavior will be identical to both values being set to 0 as previously detailed. See below for the list of accepted constants for use in the dimension expression. </dd> <dt><samp class=”option”>size, s</samp></dt> <dd> Set the video size. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size" section in the ffmpeg-utils manual. </dd> <dt><samp class=”option”>dither, d</samp></dt> <dd> Set the dither type.  <h2 class="chapter">40 CUDA Video Filters# TOC</h2>

Below is a description of the currently available Nvidia CUDA video filters. Prerequisites: <ul class="itemize mark-bullet"> Install Nvidia CUDA Toolkit

Note: If FFmpeg detects the Nvidia CUDA Toolkit during configuration, it will enable CUDA filters automatically without requiring any additional flags. If you want to explicitly enable them, use the following options: <ul class="itemize mark-bullet"> Configure FFmpeg with <code class="code">--enable-cuda-nvcc --enable-nonfree</code>. Configure FFmpeg with <code class="code">--enable-cuda-llvm</code>. Additional requirement: <code class="code">llvm</code> lib must be installed.

Running CUDA filters requires you to initialize a hardware device and to pass that device to all filters in any filter graph. <dl class="table"> <dt><samp class="option">-init_hw_device cuda[=<var class="var">name</var>][:<var class="var">device</var>[,<var class="var">key=value</var>...]]</sam
<dd> Initialise a new hardware device of type <var class="var">cuda</var> called <var class="var">name</var>, using the given device parameters. </dd> <dt><samp class="option">-filter_hw_device <var class="var">name</var></samp></dt> <dd> Pass the hardware device called <var class="var">name</var> to all filters in any filter graph. </dd> </dl>

For more detailed information see https://www.ffmpeg.org/ffmpeg.html#Advanced-Video-options <ul class="itemize mark-bullet"> Example of initializing second CUDA device on the system and running scale_cuda and bilateral_cuda filters. <pre class="example-preformatted">./ffmpeg -hwaccel cuda -hwaccel_output_format cuda -i input.mp4 -init_hw_device cuda:1 -filter_complex \ "[0:v]scale_cuda=format=yuv444p[scaled_video];[sca
\ -an -sn -c:v h264_nvenc -cq 20 out.mp4 </pre>

Since CUDA filters operate exclusively on GPU memory, frame data must sometimes be uploaded (hwupload) to hardware surfaces associated with the appropriate CUDA device before processing, and downloaded (hwdownload) back to normal memory afterward, if required. Whether hwupload or hwdownload is necessary depends on the specific workflow: <ul class="itemize mark-bullet"> If the input frames are already in GPU memory (e.g., when using <code class="code">-hwaccel cuda</code> or <code class="code">-hwaccel_output_format cuda</code>), explicit use of <a class="ref"

href=”#hwupload”>hwupload is not needed, as the data is already in the appropriate memory space. If the input frames are in CPU memory (e.g., software-decoded frames or frames processed by CPU-based filters), it is necessary to use hwupload to transfer the data to GPU memory for CUDA processing. If the output of the CUDA filters needs to be further processed by software-based filters or saved in a format not supported by GPU-based encoders, hwdownload is required to transfer the data back to CPU memory. Note that hwupload uploads data to a surface with the same layout as the software frame, so it may be necessary to add a format filter immediately before hwupload to ensure the input is in the correct format. Similarly, hwdownload may not support all output formats, so an additional format filter may need to be inserted immediately after hwdownload in the filter graph to ensure compatibility. <h3 class=”section”>40.1 bilateral_cuda# TOC</h3> CUDA accelerated bilateral filter, an edge preserving filter. This filter is mathematically accurate thanks to the use of GPU acceleration. For best output quality, use one to one chroma subsampling, i.e. yuv444p format. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sigmaS</samp></dt> <dd> Set sigma of gaussian function to calculate spatial weight, also called sigma space. Allowed range is 0.1 to 512. Default is 0.1. </dd> <dt><samp class=”option”>sigmaR</samp></dt> <dd> Set sigma of gaussian function to calculate color range weight, also called sigma color. Allowed range is 0.1 to 512. Default is 0.1. </dd> <dt><samp class=”option”>window_size</samp></dt> <dd> Set window size of the bilateral function to determine the number of neighbours to loop on. If the number entered is even, one will be added automatically. Allowed range is 1 to 255. Default is 1. </dd> </dl> <h4 class=”subsection”>40.1.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply the bilateral filter on a video.

 <pre class=”example-preformatted”>./ffmpeg -v verbose \ -hwaccel cuda -hwaccel_output_format cuda -i input.mp4 \ -init_hw_device cuda \ -filter_complex \ " \ [0:v]scale_cuda=format=yuv444p[scaled_video]; [scaled_video]bilateral_cuda=window_size=9:sigmaS=3.0:sigmaR=50.0" \ -an -sn -c:v h264_nvenc -cq 20 out.mp4 </pre>

 <h3 class="section">40.2 bwdif_cuda# TOC</h3>

Deinterlace the input video using the bwdif algorithm, but implemented in CUDA so that it can work as part of a GPU accelerated pipeline with nvdec and/or nvenc. It accepts the following parameters: <dl class="table"> <dt><samp class="option">mode</samp></dt> <dd> The interlacing mode to adopt. It accepts one of the following values: <dl class="table"> <dt><samp class="option">0, send_frame</samp></dt> <dd> Output one frame for each frame. </dd> <dt><samp class="option">1, send_field</samp></dt> <dd> Output one frame for each field. </dd> </dl>

The default value is <code class="code">send_field</code>. </dd> <dt><samp class="option">parity</samp></dt> <dd> The picture field parity assumed for the input interlaced video. It accepts one of the following values: <dl class="table"> <dt><samp class="option">0, tff</samp></dt> <dd> Assume the top field is first. </dd> <dt><samp class="option">1, bff</samp></dt> <dd> Assume the bottom field is first. </dd> <dt><samp class="option">-1, auto</samp></dt> <dd> Enable automatic detection of field parity. </dd> </dl>

The default value is <code class="code">auto</code>. If the interlacing is unknown or the decoder does not export this information, top field first will be assumed. </dd> <dt><samp class="option">deint</samp></dt> <dd> Specify which frames to deinterlace. Accepts one of the following values: <dl class="table"> <dt><samp class="option">0, all</samp></dt> <dd> Deinterlace all frames. </dd> <dt><samp class="option">1, interlaced</samp></dt> <dd> Only deinterlace frames marked as interlaced. </dd> </dl>

The default value is <code class="code">all</code>. </dd> </dl>

 <h3 class="section">40.3 chromakey_cuda# TOC</h3> CUDA accelerated YUV colorspace color/chroma keying. This filter works like normal chromakey filter but operates on CUDA frames. for more details and parameters see chromakey. <h4 class="subsection">40.3.1 Examples<span class="pull-

<ul class=”itemize mark-bullet”> Make all the green pixels in the input video transparent and use it as an overlay for another video:

 <pre class=”example-preformatted”>./ffmpeg \
-hwaccel cuda -hwaccel_output_format cuda -i input_green.mp4 \ -hwaccel cuda -hwaccel_output_format cuda -i base_video.mp4 \ -init_hw_device cuda \ -filter_complex \ " \ [0:v]chromakey_cuda=0x25302D:0.1:0.12:1[overlay_video]; \ [1:v]scale_cuda=format=yuv420p[base]; \ [base][overlay_video]overlay_cuda" \ -an -sn -c:v h264_nvenc -cq 20 output.mp4 </pre>

Process two software sources, explicitly uploading the frames:

 <pre class=”example-preformatted”>./ffmpeg -init_hw_device cuda=cuda -filter_hw_device cuda \ -f lavfi -i color=size=800x600:color=white,format=yuv42 \ -f lavfi -i yuvtestsrc=size=200x200,format=yuv420p \ -filter_complex \ " \ [0]hwupload[under]; \ [1]hwupload,chromakey_cuda=green:0.1:0.12[over]; \ [under][over]overlay_cuda" \ -c:v hevc_nvenc -cq 18 -preset slow output.mp4 </pre>

 <h3 class=”section”>40.4 colorspace_cuda# TOC</h3>

CUDA accelerated implementation of the colorspace filter. It is by no means feature complete compared to the software colorspace filter, and at the current time only supports color range conversion between jpeg/full and mpeg/limited range. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>range</samp></dt> <dd> Specify output color range. The accepted values are: <dl class=”table”> <dt>‘<samp class=”samp”>tv</samp>’</dt> <dd> TV (restricted) range </dd> <dt>‘<samp class=”samp”>mpeg</samp>’</dt> <dd> MPEG (restricted) range </dd> <dt>‘<samp class=”samp”>pc</samp>’</dt> <dd> PC (full) range </dd> <dt>‘<samp class=”samp”>jpeg</samp>’</dt> <dd> JPEG (full) range </dd> </dl>

</dd> </dl>

 <h3 class=”section”>40.5 overlay_cuda# TOC</h3>

Overlay one video on top of another. This is the CUDA variant of the overlay filter. It only accepts CUDA frames. The underlying input pixel formats have to match. It takes two inputs and has one output. The first input is the "main" video on which the second input is overlaid. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> Set expressions for the x and y coordinates of the overlaid video on the main video. They can contain the following parameters: <dl class=”table”> <dt><samp class=”option”>main_w, W</samp></dt> <dt><samp class=”option”>main_h, H</samp></dt> <dd> The main input width and height. </dd> <dt><samp class=”option”>overlay_w, w</samp></dt> <dt><samp class=”option”>overlay_h, h</samp></dt> <dd> The overlay input width and height. </dd> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> The computed values for <var class=”var”>x</var> and <var class=”var”>y</var>. They are evaluated for each new frame. </dd> <dt><samp class=”option”>n</samp></dt> <dd> The ordinal index of the main input frame, starting from 0. </dd> <dt><samp class=”option”>pos</samp></dt> <dd> The byte offset position in the file of the main input frame, NAN if unknown. Deprecated, do not use. </dd> <dt><samp class=”option”>t</samp></dt> <dd> The timestamp of the main input frame, expressed in seconds, NAN if unknown. </dd> </dl>

Default value is "0" for both expressions. </dd> <dt><samp class=”option”>eval</samp></dt> <dd> Set when the expressions for <samp class=”option”>x</samp> and <samp class=”option”>y</samp> are evaluated. It accepts the following values: <dl class=”table”> <dt><samp class=”option”>init</samp></dt> <dd> Evaluate expressions once during filter initialization or when a command is processed. </dd> <dt><samp class=”option”>frame</samp></dt> <dd> Evaluate expressions for each incoming frame </dd> </dl>

Default value is <samp class=”option”>frame</samp>. </dd> <dt><samp class=”option”>eof_action</samp></dt> <dd> See framesync. </dd> <dt><samp class=”option”>shortest</samp></dt> <dd> See framesync. </dd> <dt><samp class=”option”>repeatlast</samp></dt> <dd> See framesync. </dd> </dl>

This filter also supports the framesync options.

 <h3 class=”section”>40.6 pad_cuda<a

TOC</h3>
Add paddings to an input video stream using CUDA. This filter is the CUDA-accelerated version of the pad filter. It accepts the same options and expressions and provides the same core functionality. For a detailed description of available options, please see the documentation for the pad filter. <h4 class=”subsection”>40.6.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Add a 200-pixel black border to all sides of a video frame: <pre class=”example-preformatted”>ffmpeg -hwaccel cuda -hwaccel_output_format cuda -i input.mp4 -vf "pad_cuda=w=iw+400:h=ih+400:x=200:y=200" -c:v h264_nvenc out.mp4 </pre>

Pad the input video to a 16:9 aspect ratio, filling with the color "blue": <pre class=”example-preformatted”>ffmpeg -hwaccel cuda -hwaccel_output_format cuda -i input.mp4 -vf "pad_cuda=w=ih*16/9/sar:h=ih:x=(ow-iw)/2:y=(oh-ih)/2:color=blue" -c:v h264_nvenc out.mp4 </pre>

 <h3 class=”section”>40.7 scale_cuda#
TOC</h3>

Scale (resize) and convert (pixel format) the input video, using accelerated CUDA kernels. Setting the output width and height works in the same way as for the scale filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>w</samp></dt> <dt><samp class=”option”>h</samp></dt> <dd> Set the output video dimension expression. Default value is the input dimension. Allows for the same expressions as the scale filter. </dd> <dt><samp class=”option”>interp_algo</samp></dt> <dd> Sets the algorithm used for scaling: <dl class=”table”> <dt><var class=”var”>nearest</var></dt> <dd> Nearest neighbour Used by default if input parameters match the desired output. </dd> <dt><var class=”var”>bilinear</var></dt> <dd> Bilinear </dd> <dt><var class=”var”>bicubic</var></dt> <dd> Bicubic This is the default. </dd> <dt><var class=”var”>lanczos</var></dt> <dd> High-quality separable Lanczos (windowed sinc). The filter radius can be set with <samp class=”option”>param</samp>; the default is 3. </dd> </dl>

</dd> <dt><samp class="option">format</samp></dt> <dd> Controls the output pixel format. By default, or if none is specified, the input pixel format is used. Converting between <code class="code">yuv420p</code>, <code class="code">yuv422p</code>, <code class="code">yuv444p</code>, <code class="code">yuv420p10</code>, <code class="code">yuv422p10</code>, <code class="code">yuv444p10</code>, <code class="code">nv12</code>, <code class="code">nv16</code>, <code class="code">p010</code> or <code class="code">p210</code> and <code class="code">bgra</code>, <code class="code">rgba</code>, <code class="code">bgr0</code> or <code class="code">rgb0</code> is supported, also together with resizing. Resizing is then done on the RGB side, after converting from YUV or before converting to YUV, and always uses the generic filters selected with <samp class="option">interp_algo</samp>. Resizing the YUV side in a separate instance instead needs less intermediate memory and may be faster, but filters chroma differently. YUV to RGB conversion uses the YCbCr matrix and range of the input, RGB to YUV conversion those selected for the output (see <samp class="option">out_color_matrix</samp> and <samp class="option">out_range</samp>). An unspecified matrix is treated as BT.601 and an unspecified range as limited. The conversion samples chroma independently of <samp class="option">interp_algo</samp>: YUV to RGB conversion uses the nearest chroma sample, RGB to YUV conversion averages, which centers the chroma samples. </dd> <dt><samp class="option">passthrough</samp></dt> <dd> If set to 0, every frame is processed, even if no conversion is necessary. This mode can be useful to use the filter as a buffer for a downstream frame-consumer that exhausts the limited decoder frame pool. If set to 1, frames are passed through as-is if they match the desired output parameters. This is the default behaviour. </dd> <dt><samp class="option">use_filters</samp></dt> <dd> If set to 1, filter with a generic weight LUT instead of using fixed-function shader kernels. May be faster or slower depending on the hardware. A value of <code class="code">auto</code> (the default) enables this automatically when required for correct anti-aliasing when downscaling, and for high-quality Lanczos scaling. Set this to 0 to use the legacy fixed 4-tap Lanczos kernel. Resizing during YUV to RGB or RGB to YUV conversion always uses the generic filters. </dd> <dt><samp class="option">param</samp></dt> <dd> Algorithm-specific parameter. For <var class="var">bicubic</var>, this affects the filter curve. For <var class="var">lanczos</var>, this sets the filter radius from 1 to 10 (default 3) when using the generic filter path; it has no effect with <samp class="option">use_filters=0</samp>. </dd> <dt><samp class="option">force_original_aspect_ratio</samp></dt> <dt><samp class="option">force_divisible_by</samp></dt> <dd> Work the same as the identical scale filter options. </dd> <dt><samp class="option">reset_sar</samp></dt> <dd> Works the same as the identical scale filter option. </dd> <dt><samp class="option">out_range</samp></dt>

<dd> Set the output YCbCr sample range. One of <code class=”code”>auto</code> (the default), <code class=”code”>jpeg</code>/<code class=”code”>full</code>/<code class=”code”>pc</code>, or <code class=”code”>mpeg</code>/<code class=”code”>limited</code>/<code class=”code”>tv</code>. </dd> <dt><samp class=”option”>out_color_matrix</samp></dt> <dd> Set the output YCbCr matrix. One of <code class=”code”>auto</code> (the default), <code class=”code”>bt601</code>, <code class=”code”>smpte170m</code>, <code class=”code”>bt470</code>, <code class=”code”>bt470bg</code>, <code class=”code”>bt709</code>, <code class=”code”>fcc</code>, <code class=”code”>smpte240m</code>, <code class=”code”>ycgco</code>, <code class=”code”>bt2020</code> or <code class=”code”>bt2020nc</code>. With <code class=”code”>auto</code>, <samp class=”option”>out_range</samp> and <samp class=”option”>out_color_matrix</samp> are left to filter-graph negotiation. They follow a single range and matrix negotiated for the input, as for decoded video, and otherwise prefer BT.601 limited range. For RGB to YUV conversion, <code class=”code”>auto</code> thus means BT.601 limited range, unless the filter graph requires otherwise; converting full range YUV to RGB and back keeps the full range. Outside RGB to YUV conversion, these options describe the existing samples without remapping them; an unspecified input description may adopt the negotiated output description, while conflicting specified descriptions are rejected. Both options can only be used with YUV output; RGB output is full range. </dd> </dl>

 <h4 class=”subsection”>40.7.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Scale input to 720p, keeping aspect ratio and ensuring the output is yuv420p. <pre class=”example-preformatted”>scale_cuda=-2:720:format=yuv420p </pre>

Upscale to 4K using nearest neighbour algorithm. <pre class=”example-preformatted”>scale_cuda=4096:2160:interp_algo=nearest </pre>

Don’t do any conversion or scaling, but copy all input frames into newly allocated ones. This can be useful to deal with a filter and encode chain that otherwise exhausts the decoders frame pool. <pre class=”example-preformatted”>scale_cuda=passthrough=0 </pre>

Convert BT.709 input to RGB for a filter that requires it, then back to BT.709 NV12 with limited range. <pre class=”example-preformatted”>scale_cuda=format=bgra,scale_cuda=format=nv12:out_color_matrix=bt70 </pre>

Scale to 720p while converting to RGB.

<pre class="example-preformatted">scale_cuda=-2:720:format=bgra
</pre>

 <h3 class="section">40.8 thumbnail_cuda# TOC</h3>

Select the most representative frame in a given sequence of consecutive frames using CUDA. The filter accepts the following options: <dl class="table"> <dt><samp class="option">n</samp></dt> <dd> Set the frames batch size to analyze; in a set of <var class="var">n</var> frames, the filter will pick one of them, and then handle the next batch of <var class="var">n</var> frames until the end. Default is <code class="code">100</code>. </dd> </dl>

Since the filter keeps track of the whole frames sequence, a bigger <var class="var">n</var> value will result in a higher memory usage, so a high value is not recommended. <h4 class="subsection">40.8.1 Example# TOC</h4>

<ul class="itemize mark-bullet"> Thumbnails are extracted from every <var class="var">n</var>=150-frame batch, selecting one per batch. Chosen frames are then scaled with scale_cuda. <pre class="example-preformatted">./ffmpeg -hwaccel cuda -hwaccel_output_format cuda -i ./input.mp4 -vf "thumbnail_cuda=150,scale_cuda=1920:

The default value is <code class="code">all</code>. </dd> </dl>

 <h2 class="chapter">41 OpenCL Video Filters# TOC</h2>

Below is a description of the currently available OpenCL video filters. To enable compilation of these filters you need to configure FFmpeg with <code class="code">--enable-opencl</code>. Running OpenCL filters requires you to initialize a hardware device and to pass that device to all filters in any filter graph. <dl class="table"> <dt><samp class="option">-init_hw_device opencl[=<var class="var">name</var>][:<var class="var">device</var>[,<var class="var">key=value</var>...]]</samp> <dd> Initialise a new hardware device of type <var class="var">opencl</var> called <var class="var">name</var>, using the given device parameters. </dd> <dt><samp class="option">-filter_hw_device <var class="var">name</var></samp></dt> <dd> Pass the hardware device called <var class="var">name</var> to all filters in any filter graph. </dd> </dl>

For more detailed information see https://www.ffmpeg.org/ffmpeg.html#Advanced-Video-options <ul class="itemize mark-bullet"> Example of choosing the first device on the second platform and running avgblur_opencl filter with default parameters on it. <pre class="example-preformatted">-init_hw_device opencl=gpu:1.0 -filter_hw_device gpu -i INPUT -vf "hwupload, avgblur_opencl, hwdownload" OUTPUT </pre>

Since OpenCL filters are not able to access frame data in normal memory, all frame data needs to be uploaded(hwupload) to hardware surfaces connected to the appropriate device before being used and then downloaded(hwdownload) back to normal memory. Note that hwupload will upload to a surface with the same layout as the software frame, so it

may be necessary to add a format filter immediately before to get the input into the right format and hwdownload does not support all formats on the output - it may be necessary to insert an additional format filter immediately following in the graph to get the output in a supported format. <h3 class=”section”>41.1 avgblur_opencl# TOC</h3>

Apply average blur filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sizeX</samp></dt> <dd> Set horizontal radius size. Range is <code class=”code”>[1, 1024]</code> and default value is <code class=”code”>1</code>. </dd> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes to filter. Default value is <code class=”code”>0xf</code>, by which all planes are processed. </dd> <dt><samp class=”option”>sizeY</samp></dt> <dd> Set vertical radius size. Range is <code class=”code”>[1, 1024]</code> and default value is <code class=”code”>0</code>. If zero, <code class=”code”>sizeX</code> value will be used. </dd> </dl>

 <h4 class=”subsection”>41.1.1 Example# TOC</h4>

<ul class=”itemize mark-bullet”> Apply average blur filter with horizontal and vertical size of 3, setting each pixel of the output to the average value of the 7x7 region centered on it in the input. For pixels on the edges of the image, the region does not extend beyond the image boundaries, and so out-of-range coordinates are not used in the calculations. <pre class=”example-preformatted”>-i INPUT -vf "hwupload, avgblur_opencl=3, hwdownload" OUTPUT </pre>

 <h3 class=”section”>41.2 boxblur_opencl# TOC</h3>

Apply a boxblur algorithm to the input video. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>luma_radius, lr</samp></dt> <dt><samp class=”option”>luma_power, lp</samp></dt> <dt><samp class=”option”>chroma_radius, cr</samp></dt> <dt><samp class=”option”>chroma_power, cp</samp></dt> <dt><samp class=”option”>alpha_radius, ar</samp></dt> <dt><samp class=”option”>alpha_power, ap</samp></dt> </dl>

A description of the accepted options follows. <dl class="table">
<dt><samp class="option">luma_radius, lr</samp></dt> <dt><samp
class="option">chroma_radius, cr</samp></dt> <dt><samp class="option">alpha_radius,
ar</samp></dt> <dd> Set an expression for the box radius in pixels used
for blurring the corresponding input plane. The radius value must
be a non-negative number, and must not be greater than the value of the expression <code class="code">min(w,h)/2</code> for the luma and alpha planes,
and of <code class="code">min(cw,ch)/2</code> for the chroma planes.
 Default value for <samp class="option">luma_radius</samp> is
"2". If not specified, <samp class="option">chroma_radius</samp>
and <samp class="option">alpha_radius</samp> default to the corresponding value set for <samp class="option">luma_radius</samp>.
 The expressions can contain the following constants: <dl
class="table"> <dt><samp class="option">w</samp></dt> <dt><samp
class="option">h</samp></dt> <dd> The input width and height
in pixels. </dd> <dt><samp class="option">cw</samp></dt>
<dt><samp class="option">ch</samp></dt> <dd> The input
chroma image width and height in pixels. </dd> <dt><samp
class="option">hsub</samp></dt> <dt><samp class="option">vsub</samp></dt>
<dd> The horizontal and vertical chroma subsample values. For example,
for the pixel format "yuv422p", <var class="var">hsub</var> is
2 and <var class="var">vsub</var> is 1. </dd> </dl>

</dd> <dt><samp class="option">luma_power, lp</samp></dt>
<dt><samp class="option">chroma_power, cp</samp></dt> <dt><samp
class="option">alpha_power, ap</samp></dt> <dd> Specify how
many times the boxblur filter is applied to the corresponding plane.
Default value for <samp class="option">luma_power</samp> is 2. If
not specified, <samp class="option">chroma_power</samp> and <samp
class="option">alpha_power</samp> default to the corresponding value set
for <samp class="option">luma_power</samp>. A value of 0
will disable the effect. </dd> </dl>

 <h4 class="subsection">41.2.1 Examples# TOC</h4>

Apply boxblur filter, setting each pixel of the output to the average value of box-radiuses <var class="var">luma_radius</var>, <var
class="var">chroma_radius</var>, <var class="var">alpha_radius</var>
for each plane respectively. The filter will apply <var class="var">luma_power</var>,
<var class="var">chroma_power</var>, <var class="var">alpha_power</var>
times onto the corresponding plane. For pixels on the edges of the image,
the radius does not extend beyond the image boundaries, and so out-of-range
coordinates are not used in the calculations. <ul class="itemize
mark-bullet"> Apply a boxblur filter with the luma, chroma, and

alpha radius set to 2 and luma, chroma, and alpha power set to 3. The filter will run 3 times with box-radius set to 2 for every plane of the image. <pre class=”example-preformatted”>-i INPUT -vf "hwupload, boxblur_opencl=luma_radius=2:luma_power=3, hwdownload" OUTPUT -i INPUT -vf "hwupload, boxblur_opencl=2:3, hwdownload" OUTPUT </pre>

Apply a boxblur filter with luma radius set to 2, luma_power to 1, chroma_radius to 4, chroma_power to 5, alpha_radius to 3 and alpha_power to 7.

For the luma plane, a 2x2 box radius will be run once. For the chroma plane, a 4x4 box radius will be run 5 times. For the alpha plane, a 3x3 box radius will be run 7 times. <pre class=”example-preformatted”>-i INPUT -vf "hwupload, boxblur_opencl=2:1:4:5:3:7, hwdownload" OUTPUT </pre>

 <h3 class=”section”>41.3 colorkey_opencl# TOC</h3>
RGB colorspace color keying. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>color</samp></dt>
<dd> The color which will be replaced with transparency. </dd>
<dt><samp class=”option”>similarity</samp></dt> <dd> Similarity percentage with the key color. 0.01 matches only the exact key color, while 1.0 matches everything. </dd> <dt><samp class=”option”>blend</samp></dt> <dd> Blend percentage.
0.0 makes pixels either fully transparent, or not transparent at all.
Higher values result in semi-transparent pixels, with a higher transparency the more similar the pixels color is to the key color. </dd> </dl>

 <h4 class=”subsection”>41.3.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Make every semi-green pixel in the input transparent with some slight blending:
<pre class=”example-preformatted”>-i INPUT -vf "hwupload, colorkey_opencl=green:0.3:0.1, hwdownload" OUTPUT </pre>

 <h3 class=”section”>41.4 convolution_opencl# TOC</h3

Apply convolution of 3x3, 5x5, 7x7 matrix.  <h3 class="section">41.12 program_opencl# TOC</h3>

Filter video using an OpenCL program. <dl class="table">
<dt><samp class="option">source</samp></dt> <dd> OpenCL program source file. </dd> <dt><samp class="option">kernel</samp></dt>
<dd> Kernel name in program. </dd> <dt><samp class="option">inputs</samp></dt>
<dd> Number of inputs to the filter. Defaults to 1. </dd>
<dt><samp class="option">size, s</samp></dt> <dd> Size of output
frames. Defaults to the same as the first input. </dd> </dl>

The <code class="code">program_opencl</code> filter also supports the
framesync options. The
program source file must contain a kernel function with the given name, which
will be run once for each plane of the output. Each run on a plane gets enqueued
as a separate 2D global NDRange with one work-item for each pixel to be generated. The global ID offset for each work-item is therefore the coordinates of a
pixel in the destination image. The kernel function needs to take the
following arguments: <ul class="itemize mark-bullet"> Destination
image, <var class="var">__write_only image2d_t</var>.

This image will become the output; the kernel should write all of it.
Frame index, <var class="var">unsigned int</var>.

This is a counter starting from zero and increasing by one for each
frame. Source images, <var class="var">__read_only

image2d_t</var>.

These are the most recent images on each input. The kernel may read from them to generate the output, but they can’t be written to.

Example programs: <ul class="itemize mark-bullet"> Copy the input to the output (output must be the same size as the input). <pre class="verbatim">___kernel void copy(___write_only image2d_t destination, unsigned int index, ___read_only image2d_t source) { const sampler_t sampler = CLK_NORMALIZED_COORDS_FALSE;

int2 location = (int2)(get_global_id(0), get_global_id(1));

float4 value = read_imagef(source, sampler, location);

write_imagef(destination, location, value); } </pre> Apply a simple transformation, rotating the input by an amount increasing with the index counter. Pixel values are linearly interpolated by the sampler, and the output need not have the same dimensions as the input. <pre class="verbatim">___kernel void rotate_image(___write_only image2d_t dst, unsigned int index, ___read_only image2d_t src) { const sampler_t sampler = (CLK_NORMALIZED_COORDS_FALSE | CLK_FILTER_LINEAR);

float angle = (float)index / 100.0f;

float2 dst_dim = convert_float2(get_image_dim(dst)); float2 src_dim = convert_float2(get_image_dim(src));

float2 dst_cen = dst_dim / 2.0f; float2 src_cen = src_dim / 2.0f;

int2 dst_loc = (int2)(get_global_id(0), get_global_id(1));

float2 dst_pos = convert_float2(dst_loc) - dst_cen; float2 src_pos = { cos(angle) * dst_pos.x - sin(angle) * dst_pos.y, sin(angle) * dst_pos.x + cos(angle) * dst_pos.y }; src_pos = src_pos * src_dim / dst_dim;

float2 src_loc = src_pos + src_cen;

if (src_loc.x < 0.0f || src_loc.y < 0.0f || src_loc.x > src_dim.x || src_loc.y > src_dim.y) write_imagef(dst, dst_loc, 0.5f); else write_imagef(dst, dst_loc, read_imagef(src, sampler, src_loc)); } </pre> Blend two inputs together, with the amount of each input used varying with the index counter. <pre class="verbatim">___kernel void blend_images(___write_only image2d_t dst, unsigned int index, ___read_only image2d_t src1, ___read_only image2d_t src2) { const sampler_t sampler = (CLK_NORMALIZED_COORDS_FALSE | CLK_FILTER_LINEAR);

float blend = (cos((float)index / 50.0f) + 1.0f) / 2.0f;

int2 dst_loc = (int2)(get_global_id(0), get_global_id(1)); int2 src1_loc = dst_loc * get_image_dim(src1) / get_image_dim(dst); int2 src2_loc = dst_loc * get_image_dim(src2) / get_image_dim(dst);

float4 val1 = read_imagef(src1, sampler, src1_loc); float4 val2 = read_imagef(src2, sampler, src2_loc);

Sharpen or blur the input video. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>luma_msize_x, lx</samp></dt> <dd> Set the luma matrix horizontal size. Range is <code class=”code”>[1, 23]</code> and default value is <code class=”code”>5</code>. </dd> <dt><samp class=”option”>luma_msize_y, ly</samp></dt> <dd> Set the luma matrix vertical size. Range is <code class=”code”>[1, 23]</code> and default value is <code class=”code”>5</code>. </dd> <dt><samp class=”option”>luma_amount, la</samp></dt> <dd> Set the luma effect strength. Range is <code class=”code”>[-10, 10]</code> and default value is <code class=”code”>1.0</code>. Negative values will blur the input video, while positive values will sharpen it, a value of zero will disable the effect. </dd> <dt><samp class=”option”>chroma_msize_x, cx</samp></dt> <dd> Set the chroma matrix horizontal size. Range is <code class=”code”>[1, 23]</code> and default value is <code class=”code”>5</code>. </dd> <dt><samp class=”option”>chroma_msize_y, cy</samp></dt> <dd> Set the chroma matrix vertical size. Range is <code class=”code”>[1, 23]</code> and default value is <code class=”code”>5</code>. </dd> <dt><samp class=”option”>chroma_amount, ca</samp></dt> <dd> Set the chroma effect strength. Range is <code class=”code”>[-10, 10]</code> and default value is <code class=”code”>0.0</code>. Negative values will blur the input video, while positive values will sharpen it, a value of zero will disable the effect. </dd> </dl>

All parameters are optional and default to the equivalent of the string ’5:5:1.0:5:5:0.0’. <h4 class=”subsection”>41.17.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply strong luma sharpen effect: <pre class=”example-preformatted”>-i INPUT -vf "hwupload, unsharp_opencl=luma_msize_x=7:luma_msize_y=7:luma_amount=2.5, hwdownload" OUTPUT </pre>

Apply a strong blur of both luma and chroma parameters: <pre class=”example-preformatted”>-i INPUT -vf "hwupload, unsharp_opencl=7:7:-2:7:7:-2, hwdownload" OUTPUT </pre>

 <h3 class=”section”>41.18 xfade_opencl# TOC</h3>

Cross fade two videos with custom transition effect by using OpenCL.

 It accepts the following options: <dl class="table"> <dt><samp class="option">transition</samp></dt> <dd> Set one of possible transition effects. <dl class="table"> <dt><samp class="option">custom</samp></dt> <dd> Select custom transition effect, the actual transition description will be picked from source and kernel options. </dd> <dt><samp class="option">fade</samp></dt> <dt><samp class="option">wipeleft</samp></dt> <dt><samp class="option">wiperight</samp></dt> <dt><samp class="option">wipeup</samp></dt> <dt><samp class="option">wipedown</samp></dt> <dt><samp class="option">slideleft</samp></dt> <dt><samp class="option">slideright</samp></dt> <dt><samp class="option">slideup</samp></dt> <dt><samp class="option">slidedown</samp></dt> <dd> Default transition is fade. </dd> </dl>

</dd> <dt><samp class="option">source</samp></dt> <dd> OpenCL program source file for custom transition. </dd> <dt><samp class="option">kernel</samp></dt> <dd> Set name of kernel to use for custom transition from program source file. </dd> <dt><samp class="option">duration</samp></dt> <dd> Set duration of video transition. </dd> <dt><samp class="option">offset</samp></dt> <dd> Set time of start of transition relative to first video. </dd> </dl>

The program source file must contain a kernel function with the given name, which will be run once for each plane of the output. Each run on a plane gets enqueued as a separate 2D global NDRange with one work-item for each pixel to be generated. The global ID offset for each work-item is therefore the coordinates of a pixel in the destination image. The kernel function needs to take the following arguments: <ul class="itemize mark-bullet"> Destination image, <var class="var">__write_only image2d_t</var>.

This image will become the output; the kernel should write all of it. First Source image, <var class="var">__read_only image2d_t</var>. Second Source image, <var class="var">__read_only image2d_t</var>.

These are the most recent images on each input. The kernel may read from them to generate the output, but they can’t be written to. Transition progress, <var class="var">float</var>. This value is always between 0 and 1 inclusive.

Example programs: <ul class="itemize mark-bullet"> Apply dots curtain transition effect: <pre class="verbatim">__kernel void blend_images(__write_only image2d_t dst, __read_only image2d_t src1, __read_only image2d_t src2, float progress) { const sampler_t sampler = (CLK_NORMALIZED_COORDS_FALSE | CLK_FILTER_LINEAR); int2 p = (int2)(get_global_id(0), get_global_id(1)); float2 rp = (float2)(get_global_id(0), get_global_id(1)); float2 dim = (float2)(get_image_dim(src1).x, get_image_dim(src1).y); rp = rp / dim;

float2 dots = (float2)(20.0, 20.0); float2 center = (float2)(0,0); float2 unused;

float4 val1 = read_imagef(src1, sampler, p); float4 val2 = read_imagef(src2, sampler, p); bool next = distance(fract(rp * dots, &unused), (float2)(0.5, 0.5)) < (progress / distance(rp, center));

write_imagef(dst, p, next ? val1 : val2); } </pre>

 <h2 class="chapter">42 VAAPI Video Filters# TOC</h2>

VAAPI Video filters are usually used with VAAPI decoder and VAAPI encoder. Below is a description of VAAPI video filters. To enable compilation of these filters you need to configure FFmpeg with <code class="code">--enable-vaapi</code>. To use vaapi filters, you need to setup the vaapi device correctly. For more information, please read <a class="url" href="https://trac.ffmpeg.org/wiki/Hardware/VAAPI">https://trac.ffmpeg.org/wiki/Hardware/
  <h3 class="section">42.1 overlay_vaapi# TOC</h3>

Overlay one video on the top of another. It takes two inputs and has one output. The first input is the "main" video on which the second input is overlaid. The filter accepts the following options: <dl class="table"> <dt><samp class="option">x</samp></dt> <dt><samp class="option">y</samp></dt> <dd> Set expressions for the x and y coordinates of the overlaid video on the main video. Default value is "0" for both expressions. </dd> <dt><samp class="option">w</samp></dt> <dt><samp class="option">h</samp></dt> <dd> Set expressions for the width and height the overlaid video on the main video. Default values are ’overlay_iw’ for ’w’ and ’overlay_ih*w/overlay_iw’ for ’h’. The expressions can contain the following parameters: <dl class="table"> <dt><samp class="option">main_w, W</samp></dt> <dt><samp class="option">main_h, H</samp></dt> <dd> The main input width and height. </dd> <dt><samp class="option">overlay_iw</samp></dt> <dt><samp class="option">overlay_ih</samp></dt> <dd> The overlay input width and height. </dd> <dt><samp class="option">overlay_w, w</samp></dt> <dt><samp class="option">overlay_h, h</samp></dt> <dd> The overlay output width and height. </dd> <dt><samp class="option">overlay_x, x</samp></dt> <dt><samp class="option">overlay_y, y</samp></dt> <dd> Position of the overlay layer inside of main </dd> </dl>

</dd> <dt><samp class="option">alpha</samp></dt> <dd> Set transparency of overlaid video. Allowed range is 0.0 to 1.0. Higher value

means lower transparency. Default value is <code class="code">1.0</code>. </dd> <dt><samp class="option">eof_action</samp></dt> <dd> See framesync. </dd> <dt><samp class="option">shortest</samp></dt> <dd> See framesync. </dd> <dt><samp class="option">repeatlast</samp></dt> <dd> See framesync. </dd> </dl>

This filter also supports the framesync options. <h4 class="subsection">42.1.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Overlay an image LOGO at the top-left corner of the INPUT video. Both inputs for this filter are yuv420p format. <pre class="example-preformatted">-i INPUT -i LOGO -filter_complex "[0:v]hwupload[a], [1:v]format=yuv420p, hwupload[b], [a][b]overlay_vaapi" OUTPUT </pre> Overlay an image LOGO at the offset (200, 100) from the top-left corner of the INPUT video. The inputs have same memory layout for color channels, the overlay has additional alpha plane, like INPUT is yuv420p, and the LOGO is yuva420p. <pre class="example-preformatted">-i INPUT -i LOGO -filter_complex "[0:v]hwupload[a], [1:v]format=yuva420p, hwupload[b], [a][b]overlay_vaapi=x=200:y=100:w=400:h=300:alpha=1.0, hwdownload, format=nv12" OUTPUT </pre>

 <h3 class="section">42.2 tonemap_vaapi# TOC</h3>

Perform HDR-to-SDR or HDR-to-HDR tone-mapping. It currently only accepts HDR10 as input. It accepts the following parameters: <dl class="table"> <dt><samp class="option">format</samp></dt> <dd> Specify the output pixel format. Default is nv12 for HDR-to-SDR tone-mapping and p010 for HDR-to-HDR tone-mapping. </dd> <dt><samp class="option">primaries, p</samp></dt> <dd> Set the output color primaries. Default is bt709 for HDR-to-SDR tone-mapping and same as input for HDR-to-HDR tone-mapping. </dd> <dt><samp class="option">transfer, t</samp></dt> <dd> Set the output transfer characteristics. Default is bt709 for HDR-to-SDR tone-mapping and same as input for HDR-to-HDR tone-mapping. </dd> <dt><samp class="option">matrix, m</samp></dt> <dd> Set the output colorspace matrix. Default is bt709 for HDR-to-SDR tone-mapping and same as input for HDR-to-HDR tone-mapping.

</dd> <dt><samp class=”option”>display</samp></dt> <dd> Set the output mastering display colour volume. It is given by a ’|’-separated list of two values, two values are space separated. It set display primaries x & y in G, B, R order, then white point x & y, the nominal minimum & maximum display luminances. HDR-to-HDR tone-mapping will be performed when this option is set. </dd> <dt><samp class=”option”>light</samp></dt> <dd> Set the output content light level information. It accepts 2 space-separated values, the first input is the maximum light level and the second input is the maximum average light level. It is ignored for HDR-to-SDR tone-mapping, and optional for HDR-to-HDR tone-mapping. </dd> </dl>

</dd> </dl>

 <h2 class=”chapter”>44 Vulkan Video Filters# TOC</h2>

Below is a description of the currently available Vulkan video fil-

ters. To enable compilation of these filters you need to configure FFmpeg with <code class="code">--enable-vulkan</code>, and have a SPIR-V compiler (<code class="code">glslc</code> or <code class="code">glslangValidator</code>) available at build time. Running Vulkan filters requires you to initialize a hardware device and to pass that device to all filters in any filter graph. <dl class="table"> <dt><samp class="option">-init_hw_device vulkan[=<var class="var">name</var>][:<var class="var">device</var>[,<var class="var">key=value</var>...]]</sam
<dd> Initialise a new hardware device of type <var class="var">vulkan</var> called <var class="var">name</var>, using the given device parameters and options in <var class="var">key=value</var>. The following options are supported: <dl class="table"> <dt><samp class="option">debug</samp></dt> <dd> Switches validation layers on if set to 1. </dd> <dt><samp class="option">linear_images</samp></dt> <dd> Allocates linear images. Does not apply to decoding. </dd> <dt><samp class="option">disable_multiplane</samp></dt> <dd> Disables multiplane images. Does not apply to decoding. </dd> <dt><samp class="option">avoid_host_import</samp></dt> <dd> Avoids the use of dynamic host memory imports, in favor of a regular memcpy() into a previously mapped buffer. </dd> </dl>

</dd> <dt><samp class="option">-filter_hw_device <var class="var">name</var></samp></dt> <dd> Pass the hardware device called <var class="var">name</var> to all filters in any filter graph. </dd> </dl>

For more detailed information see https://www.ffmpeg.org/ffmpeg.html#Advanced-Video-options <ul class="itemize mark-bullet"> Example of choosing the first device and running nlmeans_vulkan filter with default parameters on it. <pre class="example-preformatted">-init_hw_device vulkan=vk:0 -filter_hw_device vk -i INPUT -vf "hwupload,nlmeans_vulkan,hwdownload" OUTPUT
</pre>

As Vulkan filters are not able to access frame data in normal memory, all frame data needs to be uploaded (hwupload) to hardware surfaces connected to the appropriate device before being used and then downloaded (hwdownload) back to normal memory. Note that hwupload will upload to a frame with the same layout as the software frame, so it may be necessary to add a format filter immediately before to get the input into the right format and hwdownload does not support all formats on the output - it is usually necessary to insert an additional format filter immediately following in the graph to get the output in a supported format. <h3 class="section">44.1

avgblur_vulkan# TOC</h3>

Apply an average blur filter, implemented on the GPU using Vulkan. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sizeX</samp></dt> <dd> Set horizontal radius size. Range is <code class=”code”>[1, 32]</code> and default value is <code class=”code”>3</code>. </dd> <dt><samp class=”option”>sizeY</samp></dt> <dd> Set vertical radius size. Range is <code class=”code”>[1, 32]</code> and default value is <code class=”code”>3</code>. </dd> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes to filter. Default value is <code class=”code”>0xf</code>, by which all planes are processed. </dd> </dl>

 <h3 class=”section”>44.2 blend_vulkan# TOC</h3>

Blend two Vulkan frames into each other. The <code class=”code”>blend</code> filter takes two input streams and outputs one stream, the first input is the "top" layer and second input is "bottom" layer. By default, the output terminates when the longest input terminates. A description of the accepted options follows. <dl class=”table”> <dt><samp class=”option”>c0_mode</samp></dt> <dt><samp class=”option”>c1_mode</samp></dt> <dt><samp class=”option”>c2_mode</samp></dt> <dt><samp class=”option”>c3_mode</samp></dt> <dt><samp class=”option”>all_mode</samp></dt> <dd> Set blend mode for specific pixel component or all pixel components in case of <var class=”var”>all_mode</var>. Default value is <code class=”code”>normal</code>. Available values for component modes are: <dl class=”table”> <dt>‘<samp class=”samp”>normal</samp>’</dt> <dt>‘<samp class=”samp”>multiply</samp>’
</dl>

</dd> </dl>

 <h2 class="chapter">46 Video Sources# TOC</h2>

Below is a description of the currently available video sources. <h3 class="section">46.1 buffer# TOC</h3>

Buffer video frames, and make them available to the filter chain. This source is mainly intended for a programmatic use, in particular through the interface defined in <samp class="file">libavfilter/buffersrc.h</samp>. It accepts the following parameters: <dl class="table"> <dt><samp class="option">video_size</samp></dt> <dd> Specify the size (width and height) of the buffered video frames. For the syntax of this option, check the <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#video-size-syntax">"Video size" section in the ffmpeg-utils manual. </dd> <dt><samp class="option">width</samp></dt> <dd> The input video width. </dd> <dt><samp class="option">height</samp></dt> <dd> The input video height. </dd> <dt><samp class="option">pix_fmt</samp></dt> <dd> A string representing the pixel format of the buffered video frames. It may be a number corresponding to a pixel format, or a pixel format name. </dd> <dt><samp class="option">time_base</samp></dt> <dd> Specify the timebase assumed by the timestamps of the buffered frames. </dd> <dt><samp class="option">frame_rate</samp></dt> <dd> Specify the frame rate expected for the video stream. </dd> <dt><samp class="option">colorspace</samp></dt> <dd> A string representing the color space of the buffered video frames. It may be a number corresponding to a color space, or a color space name. </dd> <dt><samp class="option">range</samp></dt> <dd> A string representing the color range of the buffered video frames. It may be a number corresponding to a color range, or a color range name. </dd> <dt><samp class="option">alpha_mode</samp></dt> <dd> A string representing the alpha mode of the buffered video frames. It may be a number corresponding to an alpha mode, or an alpha mode name. </dd> <dt><samp class="option">chroma_location</samp></dt> <dd> A string representing the chroma sample location of the buffered video frames. It may be a number corresponding to a chroma sample location, or a chroma sample location name. When it is not set, the filtergraph chooses the chroma sample location of the output. Frames without a chroma sample location are tagged with the one negotiated for the output. </dd> <dt><samp class="option">pixel_aspect, sar</samp></dt> <dd> The sample (pixel) aspect ratio of the input video. </dd> <dt><samp class="option">hw_frames_ctx</samp></dt> <dd> When using a hardware pixel format, this should be a reference to an AVHWFramesContext describing input frames. </dd> </dl>

For example: <pre class="example-preformatted">buffer=width=320:height=240:pix_fmt=yuv410p:time_base=1/24:sar=1
</pre>

will instruct the source to accept video frames with size 320x240 and with format "yuv410p", assuming 1/24 as the timestamps timebase and square pixels (1:1 sample aspect ratio). Since the pixel format with name "yuv410p" corresponds to the number 6 (check the enum AVPixelFormat definition in <samp class="file">libavutil/pixfmt.h</samp>), this example corresponds to: <pre class="example-preformatted">buffer=size=320x240:pixfmt=6:time_base=1/24:pixel_aspect=1/1
</pre>

Alternatively, the options can be specified as a flat string, but this syntax is deprecated: <var class="var">width</var>:<var class="var">height</var>:<var class="var">pix_fmt</var>:<var class="var">time_base.num</var>:<var class="var">time_base.den</var>:<var class="var">pixel_aspect.num</var>:<var class="var">pixel_aspect.den</var> <h3 class="section">46.2 cellauto# TOC</h3>

Create a pattern generated by an elementary cellular automaton. The initial state of the cellular automaton can be defined through the <samp class="option">filename</samp> and <samp class="option">pattern</samp> options. If such options are not specified an initial state is created randomly. At each new frame a new row in the video is filled with the result of the cellular automaton next generation. The behavior when the whole frame is filled is defined by the <samp class="option">scroll</samp> option. This source accepts the following options: <dl class="table"> <dt><samp class="option">filename, f</samp></dt> <dd> Read the initial cellular automaton state, i.e. the starting row, from the specified file. In the file, each non-whitespace character is considered an alive cell, a newline will terminate the row, and further characters in the file will be ignored. </dd> <dt><samp class="option">pattern, p</samp></dt> <dd> Read the initial cellular automaton state, i.e. the starting row, from the specified string. Each non-whitespace character in the string is considered an alive cell, a newline will terminate the row, and further characters in the string will be ignored. </dd> <dt><samp class="option">rate, r</samp></dt> <dd> Set the video rate, that is the number of frames generated per second. Default is 25. </dd> <dt><samp class="option">random_fill_ratio, ratio</samp></dt> <dd> Set the random fill ratio for the initial cellular automaton row. It is a floating point number value ranging from 0 to 1, defaults to 1/PHI. This option is ignored when a file or a pattern is specified. </dd> <dt><samp class="option">random_seed, seed</samp></dt> <dd> Set the seed for filling randomly the initial row, must be an integer included between 0 and UINT32_MAX. If not specified, or if explicitly set to -1, the filter will try to use a good random seed on a best effort basis. </dd> <dt><samp class="option">rule</samp></dt> <dd> Set the cellular automaton rule, it is a number ranging from 0 to

255. Default value is 110. </dd> <dt><samp class="option">size, s</samp></dt> <dd> Set the size of the output video. For the syntax of this option, check the <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#video-size-syntax">"Video size" section in the ffmpeg-utils manual. If <samp class="option">filename</samp> or <samp class="option">pattern</samp> is specified, the size is set by default to the width of the specified initial state row, and the height is set to <var class="var">width</var> * PHI. If <samp class="option">size</samp> is set, it must contain the width of the specified pattern string, and the specified pattern will be centered in the larger row. If a filename or a pattern string is not specified, the size value defaults to "320x518" (used for a randomly generated initial state). </dd> <dt><samp class="option">scroll</samp></dt> <dd> If set to 1, scroll the output upward when all the rows in the output have been already filled. If set to 0, the new generated row will be written over the top row just after the bottom row is filled. Defaults to 1. </dd> <dt><samp class="option">start_full, full</samp></dt> <dd> If set to 1, completely fill the output with generated rows before outputting the first frame. This is the default behavior, for disabling set the value to 0. </dd> <dt><samp class="option">stitch</samp></dt> <dd> If set to 1, stitch the left and right row edges together. This is the default behavior, for disabling set the value to 0. </dd> </dl>

 <h4 class="subsection">46.2.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Read the initial state from <samp class="file">pattern</samp>, and specify an output of size 200x400. <pre class="example-preformatted">cellauto=f=pattern:s=200x400 </pre>

Generate a random initial row with a width of 200 cells, with a fill ratio of 2/3: <pre class="example-preformatted">cellauto=ratio=2/3:s=200x200 </pre>

Create a pattern generated by rule 18 starting by a single alive cell centered on an initial row with width 100: <pre class="example-preformatted">cellauto=p=@:s=100x400:full=0:rule=18 </pre>

Specify a more elaborated initial pattern: <pre class="example-preformatted">cellauto=p='@@ @ @@':s=100x400:full=0:rule=18 </pre>

Use a core image generator at the beginning of the applied filterchain to generate the content. The coreimagesrc video source accepts the following options: <dl class=”table”> <dt><samp class=”option”>list_generators</samp></dt> <dd> List all available generators along with all their respective options as well as possible minimum and maximum values along with the default values. <pre class=”example-preformatted”>list_generators=true </pre>

</dd> <dt><samp class=”option”>size, s</samp></dt> <dd> Specify the size of the sourced video. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size" section in the ffmpeg-utils manual. The default value is <code class=”code”>320x240</code>. </dd> <dt><samp class=”option”>rate, r</samp></dt> <dd> Specify the frame rate of the sourced video, as the number of frames generated per second. It has to be a string in the format <var class=”var”>frame_rate_num</var>/<var class=”var”>frame_rate_den</var>, an integer number, a floating point number or a valid video frame rate abbreviation. The default value is "25". </dd> <dt><samp class=”option”>sar</samp></dt> <dd> Set the sample aspect ratio of the sourced video. </dd> <dt><samp class=”option”>duration, d</samp></dt> <dd> Set the duration of the sourced video. See <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#time-duration-syntax”>the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. If not specified, or the expressed duration is negative, the video is supposed to be generated forever. </dd> </dl>

Additionally, all options of the coreimage video filter are accepted. A complete filterchain can be used for further processing of the generated input without CPU-HOST transfer. See coreimage documentation and examples for details. <h4 class=”subsection”>46.3.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Use CIQRCodeGenerator to create a QR code for the FFmpeg homepage, given as complete and escaped command-line for Apple’s standard bash shell: <pre class=”example-preformatted”>ffmpeg -f lavfi -i coreimagesrc=s=100x100:filter=CIQRCodeGenerator@inputMessage=https\\\\\://FFmpeg.org/@inputCorrecti

-frames:v 1 QRCode.png </pre> This example is equivalent to the QRCode example of coreimage without the need for a nullsrc video source.

 <h3 class=”section”>46.4 ddagrab# TOC</h3>

Captures the Windows Desktop via Desktop Duplication API. The filter exclusively returns D3D11 Hardware Frames, for on-gpu encoding or processing. So an explicit hwdownload is needed for any kind of software processing. It accepts the following options: <dl class=”table”> <dt><samp class=”option”>output_idx</samp></dt> <dd> DXGI Output Index to capture. Usually corresponds to the index Windows has given the screen minus one, so it’s starting at 0. Defaults to output 0. </dd> <dt><samp class=”option”>draw_mouse</samp></dt> <dd> Whether to draw the mouse cursor. Defaults to true. Only affects hardware cursors. If a game or application renders its own cursor, it’ll always be captured. </dd> <dt><samp class=”option”>framerate</samp></dt> <dd> Maximum framerate at which the desktop will be captured - the interval between successive frames will not be smaller than the inverse of the framerate. When <var class=”var”>dup_frames</var> is true (the default) and the desktop is not being updated often enough, the filter will duplicate a previous frame. Note that there is no background buffering going on, so when the filter is not polled often enough then the actual inter-frame interval may be significantly larger. Defaults to 30 FPS. </dd> <dt><samp class=”option”>video_size</samp></dt> <dd> Specify the size of the captured video. Defaults to the full size of the screen. Cropped from the bottom/right if smaller than screen size. </dd> <dt><samp class=”option”>offset_x</samp></dt> <dd> Horizontal offset of the captured video. </dd> <dt><samp class=”option”>offset_y</samp></dt> <dd> Vertical offset of the captured video. </dd> <dt><samp class=”option”>output_fmt</samp></dt> <dd> Desired filter output format. Defaults to 8 Bit BGRA. It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Passes all supported output formats to DDA and returns what DDA decides to use. </dd> <dt>‘<samp class=”samp”>8bit</samp>’</dt> <dt>‘<samp class=”samp”>bgra</samp>’</dt> <dd> 8 Bit formats always work, and DDA will convert to them if necessary. </dd> <dt>‘<samp class=”samp”>10bit</samp>’</dt> <dt>‘<samp class=”samp”>x2bgr10</samp>’</dt> <dd> Filter initialization will fail if 10 bit format is requested but unavailable. </dd> </dl>

</dd> <dt><samp class="option">dup_frames</samp></dt> <dd> When this option is set to true (the default), the filter will duplicate frames when the desktop has not been updated in order to maintain approximately constant target framerate. When this option is set to false, the filter will wait for the desktop to be updated (inter-frame intervals may vary significantly in this case). </dd> </dl>

 <h4 class="subsection">46.4.1 Examples# TOC</h4>

Capture primary screen and encode using nvenc: <pre class="example-preformatted">ffmpeg -f lavfi -i ddagrab -c:v h264_nvenc -cq 18 output.mp4 </pre>

You can also skip the lavfi device and directly use the filter. Also demonstrates downloading the frame and encoding with libx264. Explicit output format specification is required in this case: <pre class="example-preformatted">ffmpeg -filter_complex ddagrab=output_idx=1:framerate=60,hwdownload,fo -c:v libx264 -crf 18 output.mp4 </pre>

If you want to capture only a subsection of the desktop, this can be achieved by specifying a smaller size and its offsets into the screen: <pre class="example-preformatted">ddagrab=video_size=800x600:offset_x=100:offset_y </pre>

 <h3 class="section">46.5 gfxcapture# TOC</h3>

Capture windows or monitors using Windows.Graphics.Capture API.

This source provides low overhead capture of application windows or entire monitors.

The filter outputs hardware frames in <code class="code">d3d11</code> format; use <code class="code">hwdownload,format=</code>

if system memory frames are required.

The window to be captured can be selected via regular expressions on its title,

class name or backing executable name, by explicit native handles, or by monitor

index or explicit native handle. A window must match all provided expressions to be

selected. The first matching window will be picked, in whatever order Windows

returns them.

Explicit handles (<samp class="option">hwnd</samp>, <samp class="option">hmonitor</samp>) override pattern or index

based selection. If neither handles nor a monitor index are given, the first

window matching the provided regular expressions is captured.

This source does NOT hold a stable FPS. It returns frames at whatever rate the compositor

provides them, only capped by the <samp class="option">max_framerate</samp>.

If you need a stable rate, you need to add an fps filter to drop/duplicate frames as needed.

Note that a static source may not deliver any frames at all, which also stalls

the fps filter; see <samp class="option">dup_frames</samp>.

If the capture source disappears mid-capture (window closed, monitor disconnected), the filter will return EOF.

This source accepts the following options:

<dl class="table">

<dt><samp class="option">window_title</samp></dt>

<dd> ECMAScript regular expression matched against the window title. Supports a

PCRE style <code class="code">(?i)</code> prefix for case-insensitive matching.

</dd>

<dt><samp class="option">window_class</samp></dt>

<dd> As <samp class="option">window_title</samp>, but matched against the window class name.

</dd>

<dt><samp class=”option”>window_exe</samp></dt>

<dd> As <samp class=”option”>window_title</samp>, but matched against the executable file name of the

window’s process.

</dd>

<dt><samp class=”option”>monitor_idx</samp></dt>

<dd> Zero-based index of the monitor to capture.

Can also be set to <code class=”code”>window</code> to capture the monitor the selected window

is displayed on at filter initialization time.

</dd>

<dt><samp class=”option”>hwnd</samp></dt>

<dd> Explicit native window handle (HWND).

</dd>

<dt><samp class=”option”>hmonitor</samp></dt>

<dd> Explicit native monitor handle (HMONITOR).

</dd>

<dt><samp class=”option”>capture_cursor</samp></dt>

<dd> Capture the mouse cursor. Enabled by default.

</dd>

<dt><samp class=”option”>capture_border</samp></dt>

<dd> Capture the full area of the window, including its window decorarions/border.

Disabled by default.

</dd>

<dt><samp class="option">display_border</samp></dt>

<dd> Draw a yellow highlight border around the captured window. Disabled by default.

</dd>

<dt><samp class="option">max_framerate</samp></dt>

<dd> Maximum capture frame rate. Accepts a video rate (e.g. <code class="code">30</code>, <code class="code">60/1</code>,

<code class="code">24000/1001</code>). The default is <code class="code">60</code> FPS.

The actual rate is the rate at which the compositor renders the window/monitor,

capped by this option.

</dd>

<dt><samp class="option">width</samp></dt>

<dd> Force the output canvas width. If zero (default) the initial captured source

width is used. If a negative number is provided, the width will be rounded

down to the next multiple of that number.

Supported tests are: <dl class="table"> <dt><samp class="option">dc_luma</samp></dt> <dt><samp class="option">dc_chroma</samp></dt> <dt><samp class="option">freq_luma</samp></dt> <dt><samp class="option">freq_chroma</samp></dt> <dt><samp class="option">amp_luma</samp></dt> <dt><samp class="option">amp_chroma</samp></dt> <dt><samp class="option">cbp</samp></dt> <dt><samp class="option">mv</samp></dt> <dt><samp class="option">ring1</samp></dt> <dt><samp class="option">ring2</samp></dt> <dt><samp class="option">all</samp></dt> <dt><samp class="option">max_frames, m</samp></dt> <dd> Set the maximum number of frames generated for each test, default value is 30. </dd> </dl>

Default value is "all", which will cycle through the list of all

tests. </dd> </dl>

Some examples: <pre class=”example-preformatted”>mptestsrc=t=dc_luma </pre>

will generate a "dc_luma" test pattern. <h3 class=”section”>46.9 frei0r_src# TOC</h3>

Provide a frei0r source. To enable compilation of this filter you need to install the frei0r header and configure FFmpeg with <code class=”code”>--enable-frei0r</code>. This source accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>size</samp></dt> <dd> The size of the video to generate. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size" section in the ffmpeg-utils manual. </dd> <dt><samp class=”option”>framerate</samp></dt> <dd> The framerate of the generated video. It may be a string of the form <var class=”var”>num</var>/<var class=”var”>den</var> or a frame rate abbreviation. </dd> <dt><samp class=”option”>filter_name</samp></dt> <dd> The name to the frei0r source to load. For more information regarding frei0r and how to set the parameters, read the frei0r section in the video filters documentation. </dd> <dt><samp class=”option”>filter_params</samp></dt> <dd> A ’|’-separated list of parameters to pass to the frei0r source. </dd> </dl>

For example, to generate a frei0r partik0l source with size 200x200 and frame rate 10 which is overlaid on the overlay filter main input: <pre class=”example-preformatted”>frei0r_src=size=200x200:framerate=10:filter_name=
[overlay]; [in][overlay] overlay </pre>

 <h3 class=”section”>46.10 life# TOC</h3>

Generate a life pattern.

This source is based on a generalization of John Conway’s life game.

The sourced input represents a life grid, each pixel represents a cell

which can be in one of two possible states, alive or dead. Every cell

interacts with its eight neighbours, which are the cells that are

horizontally, vertically, or diagonally adjacent.

At each interaction the grid evolves according to the adopted rule,

which specifies the number of neighbor alive cells which will make a

cell stay alive or born. The <samp class="option">rule</samp> option allows one to specify

the rule to adopt.

This source accepts the following options:

<dl class="table">

<dt><samp class="option">filename, f</samp></dt>

<dd> Set the file from which to read the initial grid state. In the file,

each non-whitespace character is considered an alive cell, and newline

is used to delimit the end of each row.

If this option is not specified, the initial grid is generated

randomly.

</dd>

<dt><samp class="option">rate, r</samp></dt>

<dd> Set the video rate, that is the number of frames generated per second.

Default is 25.

</dd>

<dt><samp class="option">random_fill_ratio, ratio</samp></dt>

<dd> Set the random fill ratio for the initial random grid. It is a

floating point number value ranging from 0 to 1, defaults to 1/PHI.

It is ignored when a file is specified.

</dd>

<dt><samp class=”option”>random_seed, seed</samp></dt>

<dd> Set the seed for filling the initial random grid, must be an integer

included between 0 and UINT32_MAX. If not specified, or if explicitly

set to -1, the filter will try to use a good random seed on a best

effort basis.

</dd>

<dt><samp class=”option”>rule</samp></dt>

<dd> Set the life rule.

A rule can be specified with a code of the kind "S<var class=”var”>NS</var>/B<var class=”var”>NB</var>",

where <var class=”var”>NS</var> and <var class=”var”>NB</var> are sequences of numbers in the range 0-8,

<var class=”var”>NS</var> specifies the number of alive neighbor cells which make a

live cell stay alive, and <var class=”var”>NB</var> the number of alive neighbor cells

which make a dead cell to become alive (i.e. to "born").

"s" and "b" can be used in place of "S" and "B", respectively.

Alternatively a rule can be specified by an 18-bits integer. The 9

high order bits are used to encode the next cell state if it is alive

for each number of neighbor alive cells, the low order bits specify

the rule for "borning" new cells. Higher order bits encode for an

higher number of neighbor cells.

For example the number 6153 = <code class=”code”>(12<<9)+9</code> specifies a stay alive

rule of 12 and a born rule of 9, which corresponds to "S23/B03".

Default value is "S23/B3", which is the original Conway’s game of life

rule, and will keep a cell alive if it has 2 or 3 neighbor alive

cells, and will born a new cell if there are three alive cells around

a dead cell.

</dd>

<dt><samp class=”option”>size, s</samp></dt>

<dd> Set the size of the output video. For the syntax of this option, check the

<a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size" section in the ffmpeg-utils manual.

If <samp class=”option”>filename</samp> is specified, the size is set by default to the

same size of the input file. If <samp class=”option”>size</samp> is set, it must contain

the size specified in the input file, and the initial grid defined in

that file is centered in the larger resulting area.

If a filename is not specified, the size value defaults to "320x240"

(used for a randomly generated initial grid).

</dd>

<dt><samp class=”option”>stitch</samp></dt>

<dd> If set to 1, stitch the left and right grid edges together, and the

top and bottom edges also. Defaults to 1.

</dd>

<dt><samp class=”option”>mold</samp></dt>

<dd> Set cell mold speed. If set, a dead cell will go from <samp class=”option”>death_color</samp> to

<samp class=”option”>mold_color</samp> with a step of <samp class=”option”>mold</samp>. <samp class=”option”>mold</samp> can have a

value from 0 to 255.

</dd>

<dt><samp class="option">life_color</samp></dt>

<dd> Set the color of living (or new born) cells.

</dd>

<dt><samp class="option">death_color</samp></dt>

<dd> Set the color of dead cells. If <samp class="option">mold</samp> is set, this is the first color

used to represent a dead cell.

</dd>

<dt><samp class="option">mold_color</samp></dt>

<dd> Set mold color, for definitely dead and moldy cells.

For the syntax of these 3 color options, check the <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#color-syntax">"Color" section in the

ffmpeg-utils manual.

</dd>

</dl>

allrgb, allyuv, color, colorchart, colorspectrum, haldclutsrc, nullsrc, pal75bars, pal100bars, rgbtestsrc, smptebars, smptehdbars, testsrc, testsrc2, yuvtestsrc# TOC</h3>

The <code class="code">allrgb</code> source returns frames of size 4096x4096 of all rgb colors.

The <code class="code">allyuv</code> source returns frames of size 4096x4096 of all yuv colors.

The <code class="code">color</code> source provides an uniformly colored input.

The <code class="code">colorchart</code> source provides a colors checker chart.

The <code class="code">colorspectrum</code> source provides a color spectrum input.

The <code class="code">haldclutsrc</code> source provides an identity Hald CLUT. See also

haldclut filter.

The <code class="code">nullsrc</code> source returns unprocessed video frames. It is

mainly useful to be employed in analysis / debugging tools, or as the

source for filters which ignore the input data.

The <code class="code">pal75bars</code> source generates a color bars pattern, based on

EBU PAL recommendations with 75% color levels.

The <code class=”code”>pal100bars</code> source generates a color bars pattern, based on

EBU PAL recommendations with 100% color levels.

The <code class=”code”>rgbtestsrc</code> source generates an RGB test pattern useful for

detecting RGB vs BGR issues. You should see a red, green and blue

stripe from top to bottom.

The <code class=”code”>smptebars</code> source generates a color bars pattern, based on

the SMPTE Engineering Guideline EG 1-1990.

The <code class=”code”>smptehdbars</code> source generates a color bars pattern, based on

the SMPTE RP 219-2002.

The <code class=”code”>testsrc</code> source generates a test video pattern, showing a

color pattern, a scrolling gradient and a timestamp. This is mainly

intended for testing purposes.

The <code class=”code”>testsrc2</code> source is similar to testsrc, but supports more

pixel formats instead of just <code class=”code”>rgb24</code>. This allows using it as an

input for other tests without requiring a format conversion.

The <code class=”code”>yuvtestsrc</code> source generates an YUV test pattern. You should

see a y, cb and cr stripe from top to bottom.

The sources accept the following parameters:

<dl class="table">

<dt><samp class="option">level</samp></dt>

<dd> Specify the level of the Hald CLUT, only available in the <code class="code">haldclutsrc</code>

source. A level of <code class="code">N</code> generates a picture of <code class="code">N*N*N</code> by <code class="code">N*N*N</code>

pixels to be used as identity matrix for 3D lookup tables. Each component is

coded on a <code class="code">1/(N*N)</code> scale.

</dd>

<dt><samp class="option">color, c</samp></dt>

<dd> Specify the color of the source, only available in the <code class="code">color</code>

source. For the syntax of this option, check the

<a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#color-syntax">"Color" section in the ffmpeg-utils manual.

</dd>

<dt><samp class="option">size, s</samp></dt>

<dd> Specify the size of the sourced video. For the syntax of this option, check the

<a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#video-size-syntax">"Video size" section in the ffmpeg-utils manual.

The default value is <code class="code">320x240</code>.

This option is not available with the <code class="code">allrgb</code>, <code class="code">allyuv</code>, and

<code class="code">haldclutsrc</code> filters.

</dd>

<dt><samp class="option">rate, r</samp></dt>

<dd> Specify the frame rate of the sourced video, as the number of frames

generated per second. It has to be a string in the format

<var class="var">frame_rate_num</var>/<var class="var">frame_rate_den</var>, an integer number, a floating point

number or a valid video frame rate abbreviation. The default value is

"25".

</dd>

<dt><samp class="option">duration, d</samp></dt>

<dd> Set the duration of the sourced video. See

<a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#time-duration-syntax">the Time duration section in the ffmpeg-utils(1) manual

for the accepted syntax.

If not specified, or the expressed duration is negative, the video is

supposed to be generated forever.

Since the frame rate is used as time base, all frames including the last one

will have their full duration. If the specified duration is not a multiple

of the frame duration, it will be rounded up.

</dd>

<dt><samp class="option">sar</samp></dt>

<dd> Set the sample aspect ratio of the sourced video.

</dd>

<dt><samp class="option">alpha</samp></dt>

<dd> Specify the alpha (opacity) of the background, only available in the

<code class="code">testsrc2</code> source. The value must be between 0 (fully transparent) and

255 (fully opaque, the default).

</dd>

<dt><samp class=”option”>decimals, n</samp></dt>

<dd> Set the number of decimals to show in the timestamp, only available in the

<code class=”code”>testsrc</code> source.

The displayed timestamp value will correspond to the original

timestamp value multiplied by the power of 10 of the specified

value. Default value is 0.

</dd>

<dt><samp class=”option”>type</samp></dt>

<dd> Set the type of the color spectrum, only available in the

<code class=”code”>colorspectrum</code> source. Can be one of the following:

<dl class=”table”>

<dt>‘<samp class=”samp”>black</samp>’</dt>

<dt>‘<samp class=”samp”>white</samp>’</dt>

<dt>‘<samp class=”samp”>all</samp>’</dt>

</dl>

</dd> <dt><samp class=”option”>patch_size</samp></dt> <dd> Set patch size of single color patch, only available in the <code class=”code”>colorchart</code> source. Default is <code class=”code”>64x64</code>. </dd> <dt><samp class=”option”>preset</samp></dt> <dd> Set colorchecker colors preset, only available in the <code class=”code”>colorchart</code> source. Available values are: <dl class=”table”> <dt>‘<samp class=”samp”>reference</samp>’</dt> <dt>‘<samp class=”samp”>skintones</samp>’</dt> </dl>

Default value is <code class=”code”>reference</code>. </dd> </dl>

 <h4 class="subsection">46.13.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Generate a video with a duration of 5.3 seconds, with size 176x144 and a frame rate of 10 frames per second: <pre class="example-preformatted">testsrc=duration=5.3:size=qcif:rate=10 </pre>

The following graph description will generate a red source with an opacity of 0.2, with size "qcif" and a frame rate of 10 frames per second: <pre class="example-preformatted">color=c=red@0.2:s=qcif:r=10 </pre>

If the input content is to be ignored, <code class="code">nullsrc</code> can be used. The following command generates noise in the luma plane by employing the <code class="code">geq</code> filter: <pre class="example-preformatted">nullsrc=s=256x256, geq=random(1)*255:128:128 </pre>

 <h4 class="subsection">46.13.2 Commands# TOC</h4>

The <code class="code">color</code> source supports the following commands: <dl class="table"> <dt><samp class="option">c, color</samp></dt> <dd> Set the color of the created image. Accepts the same syntax of the corresponding <samp class="option">color</samp> option. </dd> </dl>

 <h3 class="section">46.14 openclsrc# TOC</h3>

Generate video using an OpenCL program. <dl class="table"> <dt><samp class="option">source</samp></dt> <dd> OpenCL program source file. </dd> <dt><samp class="option">kernel</samp></dt> <dd> Kernel name in program. </dd> <dt><samp class="option">size, s</samp></dt> <dd> Size of frames to generate.   <h3 class="section">48.8 bench, abench# TOC</h3>

Benchmark part of a filtergraph. The filter accepts the following options: <dl class="table"> <dt><samp class="option">action</samp></dt>
<dd> Start or stop a timer. Available values are: <dl class="table"> <dt>‘<samp class="samp">start</samp>’</dt>
<dd> Get the current time, set it as frame metadata (using the key <code class="code">lavfi.bench.start_time</code>), and forward the frame to the next filter. </dd> <dt>‘<samp class="samp">stop</samp>’</dt>
<dd> Get the current time and fetch the <code class="code">lavfi.bench.start_time</code> metadata from the input frame metadata to get the time difference. Time difference, average, maximum and minimum time (respectively <code class="code">t</code>, <code class="code">avg</code>, <code class="code">max</code> and <code class="code">min</code>) are then printed. The timestamps are expressed in seconds. </dd> </dl> </dd>
</dl>

 <h4 class="subsection">48.8.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Benchmark selectivecolor

filter: <pre class=”example-preformatted”>bench=start,selectivecolor=reds=-.2 .12 -.49,bench=stop </pre>

 <h3 class=”section”>48.9 concat# TOC</h3>

Concatenate audio and video streams, joining them together one after the other. The filter works on segments of synchronized video and audio streams. All segments must have the same number of streams of each type, and that will also be the number of streams at output. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>n</samp></dt> <dd> Set the number of segments. Default is 2. </dd> <dt><samp class=”option”>v</samp></dt> <dd> Set the number of output video streams, that is also the number of video streams in each segment. Default is 1. </dd> <dt><samp class=”option”>a</samp></dt> <dd> Set the number of output audio streams, that is also the number of audio streams in each segment. Default is 0. </dd> <dt><samp class=”option”>unsafe</samp></dt> <dd> Activate unsafe mode: do not fail if segments have a different format. </dd> </dl>

The filter has <var class=”var”>v</var>+<var class=”var”>a</var> outputs: first <var class=”var”>v</var> video outputs, then <var class=”var”>a</var> audio outputs. There are <var class=”var”>n</var>x(<var class=”var”>v</var>+<var class=”var”>a</var>) inputs: first the inputs for the first segment, in the same order as the outputs, then the inputs for the second segment, etc. Related streams do not always have exactly the same duration, for various reasons including codec frame size or sloppy authoring. For that reason, related synchronized streams (e.g. a video and its audio track) should be concatenated at once. The concat filter will use the duration of the longest stream in each segment (except the last one), and if necessary pad shorter audio streams with silence. For this filter to work correctly, all segments must start at timestamp 0. All corresponding streams must have the same parameters in all segments; the filtering system will automatically select a common pixel format for video streams, and a common sample format, sample rate and channel layout for audio streams, but other settings, such as resolution, must be converted explicitly by the user. Different frame rates are acceptable but will result in variable frame rate at output; be sure to configure the output file to handle it. <h4 class=”subsection”>48.9.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Concatenate an opening, an episode and an ending, all in bilingual version (video in stream 0, audio in streams 1 and 2):

 <pre class="example-preformatted">ffmpeg -i opening.mkv -i episode.mkv -i ending.mkv -filter_complex \ '[0:0] [0:1] [0:2] [1:0] [1:1] [1:2] [2:0] [2:1] [2:2] concat=n=3:v=1:a=2 [v] [a1] [a2]' \ -map '[v]' -map '[a1]' -map '[a2]' output.mkv </pre>

Concatenate two parts, handling audio and video separately, using the (a)movie sources, and adjusting the resolution: <pre class="example-preformatted">movie=part1.mp4, scale=512:288 [v1] ; amovie=part1.mp4 [a1] ; movie=part2.mp4, scale=512:288 [v2] ; amovie=part2.mp4 [a2] ; [v1] [v2] concat [outv] ; [a1] [a2] concat=v=0:a=1 [outa] </pre> Note that a desync will happen at the stitch if the audio and video streams do not have exactly the same duration in the first file.

 <h4 class="subsection">48.9.2 Commands# TOC</h4>

This filter supports the following commands: <dl class="table"> <dt><samp class="option">next</samp></dt> <dd> Close the current segment and step to the next one </dd> </dl>

 <h3 class="section">48.10 ebur128# TOC</h3>

EBU R128 scanner filter. This filter takes an audio stream and analyzes its loudness level. By default, it logs a message at a frequency of 10Hz with the Momentary loudness (identified by <code class="code">M</code>), Short-term loudness (<code class="code">S</code>), Integrated loudness (<code class="code">I</code>) and Loudness Range (<code class="code">LRA</code>). The filter can only analyze streams which have sample format is double-precision floating point. The input stream will be converted to this specification, if needed. Users may need to insert aformat and/or aresample filters after this filter to obtain the original parameters. The filter also has a video output (see the <var class="var">video</var> option) with a real time graph to observe the loudness evolution. The graphic contains the logged message mentioned above, so it is not printed anymore when this option is set, unless the verbose logging is set. The main graphing area contains the short-term loudness (3 seconds of analysis), and the gauge on the right is for the momentary loudness (400 milliseconds), but can optionally be configured to instead display short-term loudness (see <var class="var">gauge</var>). The green area marks a +/- 1LU target range around the target loudness (-23LUFS by default, unless modified through <var class="var">target</var>). More information about the Loudness Recommendation EBU R128 on <a class="url"

href=”http://tech.ebu.ch/loudness”>http://tech.ebu.ch/loudness. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>video</samp></dt> <dd> Activate the video output. The audio stream is passed unchanged whether this option is set or no. The video stream will be the first output stream if activated. Default is <code class=”code”>0</code>. </dd> <dt><samp class=”option”>size</samp></dt> <dd> Set the video size. This option is for video only. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size" section in the ffmpeg-utils manual. Default and minimum resolution is <code class=”code”>640x480</code>. </dd> <dt><samp class=”option”>meter</samp></dt> <dd> Set the EBU scale meter. Default is <code class=”code”>9</code>. Common values are <code class=”code”>9</code> and <code class=”code”>18</code>, respectively for EBU scale meter +9 and EBU scale meter +18. Any other integer value between this range is allowed. </dd> <dt><samp class=”option”>metadata</samp></dt> <dd> Set metadata injection. If set to <code class=”code”>1</code>, the audio input will be segmented into 100ms output frames, each of them containing various loudness information in metadata. All the metadata keys are prefixed with <code class=”code”>lavfi.r128.</code>. Default is <code class=”code”>0</code>. </dd> <dt><samp class=”option”>framelog</samp></dt> <dd> Force the frame logging level. Available values are: <dl class=”table”> <dt>‘<samp class=”samp”>quiet</samp>’</dt> <dd> logging disabled </dd> <dt>‘<samp class=”samp”>info</samp>’</dt> <dd> information logging level </dd> <dt>‘<samp class=”samp”>verbose</samp>’</dt> <dd> verbose logging level </dd> </dl>

By default, the logging level is set to <var class=”var”>info</var>. If the <samp class=”option”>video</samp> or the <samp class=”option”>metadata</samp> options are set, it switches to <var class=”var”>verbose</var>. </dd> <dt><samp class=”option”>peak</samp></dt> <dd> Set peak mode(s). Available modes can be cumulated (the option is a <code class=”code”>flag</code> type). Possible values are: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> Disable any peak mode (default). </dd> <dt>‘<samp class=”samp”>sample</samp>’</dt> <dd> Enable sample-peak mode. Simple peak mode looking for the higher sample value. It logs a message for sample-peak (identified by <code class=”code”>SPK</code>). </dd> <dt>‘<samp class=”samp”>true</samp>’</dt> <dd> Enable true-peak mode. If enabled, the peak lookup is done on an over-sampled version of the input stream for better peak accuracy. It logs a message for true-peak. (identified by <code class=”code”>TPK</code>) and true-peak per frame (identified by <code class=”code”>FTPK</code>). This mode requires a build with <code

class=”code”>libswresample</code>. </dd> </dl>

</dd> <dt><samp class=”option”>dualmono</samp></dt> <dd> Treat mono input files as "dual mono". If a mono file is intended for playback on a stereo system, its EBU R128 measurement will be perceptually incorrect. If set to <code class=”code”>true</code>, this option will compensate for this effect.  <h3 class="section">48.11 interleave, ainterleave# TOC</h3>

Temporally interleave frames from several inputs. <code class="code">interleave</code> works with video inputs, <code class="code">ainterleave</code> with audio. These filters read frames from several inputs and send the oldest queued frame to the output. Input streams must have well defined, monotonically increasing frame timestamp values. In order to submit one frame to output, these filters need to enqueue at least one frame for each input, so they cannot work in case one input is not yet terminated and will not receive incoming frames. For example consider the case when one input is a <code class="code">select</code> filter which always drops input frames. The <code class="code">interleave</code> filter will keep reading from that input, but it will never be able to send new frames to output until the input sends an end-of-stream signal. Also, depending on inputs synchronization, the filters will drop frames in case one input receives more frames than the other ones, and the queue is already filled. These filters accept the following options: <dl class="table"> <dt><samp class="option">nb_inputs, n</samp></dt> <dd> Set the number of different inputs, it is 2 by default. </dd> <dt><samp class="option">duration</samp></dt> <dd> How to determine the end-of-stream. <dl class="table"> <dt><samp class="option">longest</samp></dt> <dd> The duration of the longest input.  <h4 class=”subsection”>48.13.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Print all metadata values for frames with key <code class=”code”>lavfi.signalstats.YDIF</code> with val-

ues between 0 and 1. <pre class=”example-preformatted”>signalstats,metadata=print:key=lavfi.signalstats.YDIF:value=0:function=expr:expr='between
</pre> Print silencedetect output to file <samp class=”file”>metadata.txt</samp>.
 <pre class=”example-preformatted”>silencedetect,ametadata=mode=print:file=meta
</pre> Direct all metadata to a pipe with file descriptor 4.
 <pre class=”example-preformatted”>metadata=mode=print:file='pipe\:4'
</pre>

 <h3 class=”section”>48.14 perms, aperms# TOC</h3>

Set read/write permissions for the output frames. These filters are mainly aimed at developers to test direct path in the following filter in the filtergraph. The filters accept the following options: <dl class=”table”> <dt><samp class=”option”>mode</samp></dt>
<dd> Select the permissions mode. It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt>
<dd> Do nothing. This is the default. </dd> <dt>‘<samp class=”samp”>ro</samp>’</dt> <dd> Set all the output frames read-only. </dd> <dt>‘<samp class=”samp”>rw</samp>’</dt>
<dd> Set all the output frames directly writable. </dd>
<dt>‘<samp class=”samp”>toggle</samp>’</dt> <dd> Make the frame read-only if writable, and writable if read-only. </dd>
<dt>‘<samp class=”samp”>random</samp>’</dt> <dd> Set each output frame read-only or writable randomly. </dd> </dl>

</dd> <dt><samp class=”option”>seed</samp></dt> <dd> Set the seed for the <var class=”var”>random</var> mode, must be an integer included between <code class=”code”>0</code> and <code class=”code”>UINT32_MAX</code>. If not specified, or if explicitly set to <code class=”code”>-1</code>, the filter will try to use a good random seed on a best effort basis. </dd> </dl>

Note: in case of auto-inserted filter between the permission filter and the following one, the permission might not be received as expected in that following filter. Inserting a format or aformat filter before the perms/aperms filter can avoid this problem. <h3 class=”section”>48.15 realtime, arealtime# TOC</h3>

Slow down filtering to match real time approximately. These filters will pause the filtering for a variable amount of time to match the output rate with the input timestamps. They are similar to the <samp

class=”option”>re</samp> option to <code class=”code”>ffmpeg</code>. They accept the following options: <dl class=”table”> <dt><samp class=”option”>limit</samp></dt> <dd> Time limit for the pauses. Any pause longer than that will be considered a timestamp discontinuity and reset the timer. Default is 2 seconds. </dd> <dt><samp class=”option”>speed</samp></dt> <dd> Speed factor for processing. The value must be a float larger than zero. Values larger than 1.0 will result in faster than realtime processing, smaller will slow processing down. The <var class=”var”>limit</var> is automatically adapted accordingly. Default is 1.0. A processing speed faster than what is possible without these filters cannot be achieved. </dd> </dl>

 <h4 class=”subsection”>48.15.1 Commands# TOC</h4>

Both filters supports the all above options as commands. <h3 class=”section”>48.16 segment, asegment# TOC</h3

Split single input stream into multiple streams. This filter does opposite of concat filters. <code class=”code”>segment</code> works on video frames, <code class=”code”>asegment</code> on audio samples. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>timestamps</samp></dt> <dd> Timestamps of output segments separated by ’|’. The first segment will run from the beginning of the input stream. The last segment will run until the end of the input stream </dd> <dt><samp class=”option”>frames, samples</samp></dt> <dd> Exact frame/sample count to split the segments. </dd> </dl>

In all cases, prefixing an each segment with ’+’ will make it relative to the previous segment. <h4 class=”subsection”>48.16.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Split input audio stream into three output audio streams, starting at start of input audio stream and storing that in 1st output audio stream, then following at 60th second and storing than in 2nd output audio stream, and last after 150th second of input audio stream store in 3rd output audio stream: <pre class=”example-preformatted”>asegment=timestamps="60|150" </pre>

<h3 class=”section”>48.17 select, aselect<a
class=”anchor hidden-xs” href=”#select_002c-aselect” aria-hidden=”true”>#
TOC</h3>

Select frames to pass in output. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>expr, e</samp></dt> <dd> Set expression, which is evaluated for each input frame. If the expression is evaluated to zero, the frame is discarded. If the evaluation result is negative or NaN, the frame is sent to the first output; otherwise it is sent to the output with index <code class=”code”>ceil(val)-1</code>, assuming that the input index starts from 0. For example a value of <code class=”code”>1.2</code> corresponds to the output with index <code class=”code”>ceil(1.2)-1 = 2-1 = 1</code>, that is the second output. </dd> <dt><samp class=”option”>outputs, n</samp></dt> <dd> Set the number of outputs. The output to which to send the selected frame is based on the result of the evaluation. Default value is 1. </dd> </dl>

The expression can contain the following constants: <dl class=”table”> <dt><samp class=”option”>n</samp></dt> <dd> The (sequential) number of the filtered frame, starting from 0. </dd> <dt><samp class=”option”>selected_n</samp></dt> <dd> The (sequential) number of the selected frame, starting from 0. </dd> <dt><samp class=”option”>prev_selected_n</samp></dt> <dd> The sequential number of the last selected frame. <dt><samp class=”option”>S</samp></dt> <dt><samp class=”option”>SI</samp></dt>
<dt><samp class=”option”>SP</samp></dt> <dt><samp class=”option”>BI</samp></dt>
</dl>

</dd> <dt><samp class=”option”>interlace_type (video
only)</samp></dt> <dd> The frame interlace type. It can assume one of the following values: <dl class=”table”> <dt><samp
class=”option”>PROGRESSIVE</samp></dt> <dd> The frame is progressive (not interlaced). </dd> <dt><samp class=”option”>TOPFIRST</samp></dt>
<dd> The frame is top-field-first. </dd> <dt><samp class=”option”>BOTTOMFIRST</samp><
<dd> The frame is bottom-field-first. </dd> </dl>

</dd> <dt><samp class=”option”>consumed_sample_n (audio
only)</samp></dt> <dd> the number of selected samples before
the current frame </dd> <dt><samp class=”option”>samples_n
(audio only)</samp></dt> <dd> the
number of samples in the current frame </dd> <dt><samp
class=”option”>sample_rate (audio only)</samp></dt>
<dd> the input sample rate </dd> <dt><samp class=”option”>key</samp></dt>
<dd> This is 1 if the filtered frame is a key-frame, 0 otherwise.
</dd> <dt><samp class=”option”>pos</samp></dt> <dd> the
position in the file of the filtered frame, -1 if the information is not
available (e.g. for synthetic video); deprecated, do not use
</dd> <dt><samp class=”option”>scene (video
only)</samp></dt> <dd> value between 0 and 1 to indicate
a new scene; a low value reflects a low probability for the current frame
to introduce a new scene, while a higher value means the current frame is
more likely to be one (see the example below) </dd> <dt><samp
class=”option”>concatdec_select</samp></dt> <dd> The concat
demuxer can select only part of a concat input file by setting an inpoint
and an outpoint, but the output packets may not be entirely contained
in the selected interval. By using this variable, it is possible to skip
frames generated by the concat demuxer which are not exactly contained
in the selected interval. This works by comparing the frame
pts against the <var class=”var”>lavf.concat.start_time</var> and the
<var class=”var”>lavf.concat.duration</var> packet metadata values
which are also present in the decoded frames. The <var
class=”var”>concatdec_select</var> variable is -1 if the frame pts is at least
start_time and either the duration metadata is missing or the frame pts is
less than start_time + duration, 0 otherwise, and NaN if the start_time
metadata is missing. That basically means that an input frame
is selected if its pts is within the interval set by the concat demuxer.
 </dd> <dt><samp class=”option”>iw (video
only)</samp></dt> <dd> Represents the width of the input video frame. </dd> <dt><samp class=”option”>ih <em
class=”emph”>(video only)</samp></dt> <dd> Represents the

height of the input video frame. </dd> <dt><samp class="option">view (video only)</samp></dt> <dd> View ID for multi-view video. </dd> </dl>

The default value of the select expression is "1". <h4 class="subsection">48.17.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Select all frames in input: <pre class="example-preformatted">select </pre>

The example above is the same as: <pre class="example-preformatted">select=1 </pre>

Skip all frames: <pre class="example-preformatted">select=0 </pre>

Select only I-frames: <pre class="example-preformatted">select='eq(pict_type\,I)' </pre>

Select one frame every 100: <pre class="example-preformatted">select='not(mod(n\,100))' </pre>

Select only frames contained in the 10-20 time interval: <pre class="example-preformatted">select=between(t\,10\,20) </pre>

Select only I-frames contained in the 10-20 time interval: <pre class="example-preformatted">select=between(t\,10\,20)*eq(pict_type\,I) </pre>

Select frames with a minimum distance of 10 seconds: <pre class="example-preformatted">select='isnan(prev_selected_t)+gte(t-prev_selected_t\,10)' </pre>

Use aselect to select only audio frames with samples number > 100: <pre class="example-preformatted">aselect='gt(samples_n\,100)' </pre>

Create a mosaic of the first scenes: <pre class="example-preformatted">ffmpeg -i video.avi -vf select='gt(scene\,0.4)',scale=160:120,tile -frames:v 1 preview.png </pre>

Comparing <var class="var">scene</var> against a value between 0.3 and 0.5 is generally a sane choice. Send even and odd frames to separate outputs, and compose them: <pre class="example-preformatted">select=n=2:e='mod(n, 2)+1' [odd][even]; [odd] pad=h=2*ih [tmp]; [tmp][even] overlay=y=h </pre>

Select useful frames from an ffconcat file which is using inpoints and outpoints but where the source files are not intra frame only. <pre class="example-preformatted">ffmpeg -copyts -segment_time_metadata 1 -i input.ffconcat -fps_mode passthrough -vf select=concatdec_select -af aselect=concatdec_select output.avi </pre>

 <h3 class="section">48.18 sendcmd, asendcmd# TOC</h3>

Send commands to filters in the filtergraph. These filters read commands to be sent to other filters in the filtergraph. <code class="code">sendcmd</code> must be inserted between two video filters, <code class="code">asendcmd</code> must be inserted between two audio filters, but apart from that they act the same way. The specification of commands can be provided in the filter arguments with the <var class="var">commands</var> option, or in a file specified by the <var class="var">filename</var> option. These filters accept the following options: <dl class="table"> <dt><samp class="option">commands, c</samp></dt> <dd> Set the commands to be read and sent to the other filters. </dd> <dt><samp class="option">filename, f</samp></dt> <dd> Set the filename of the commands to be read and sent to the other filters. </dd> </dl>

 <h4 class="subsection">48.18.1 Commands syntax# TOC</h4>

A commands description consists of a sequence of interval specifications, comprising a list of commands to be executed when a particular event related to that interval occurs. The occurring event is typically the current frame time entering or leaving a given time interval. An interval is specified by the following syntax: <pre class="example-preformatted"><var class="var">START</var>[-<var class="var">END</var>] <var class="var">COMMANDS</var>; </pre>

The time interval is specified by the <var class="var">START</var> and <var class="var">END</var> times. <var class="var">END</var> is optional and defaults to the maximum time. The current frame time is considered within the specified interval if it is included in the interval [<var class="var">START</var>, <var class="var">END</var>), that is when the time is greater or equal to <var class="var">START</var> and is lesser than <var class="var">END</var>. <var

class=”var”>COMMANDS</var> consists of a sequence of one or more command specifications, separated by ",", relating to that interval. The syntax of a command specification is given by: <pre class=”example-preformatted”>[<var class=”var”>FLAGS</var>] <var class=”var”>TARGET</var> <var class=”var”>COMMAND</var> <var class=”var”>ARG</var> </pre>

<var class=”var”>FLAGS</var> is optional and specifies the type of events relating to the time interval which enable sending the specified command, and must be a non-null sequence of identifier flags separated by "+" or "|" and enclosed between "[" and "]". The following flags are recognized: <dl class=”table”> <dt><samp class=”option”>enter</samp></dt> <dd> The command is sent when the current frame timestamp enters the specified interval. In other words, the command is sent when the previous frame timestamp was not in the given interval, and the current is. </dd> <dt><samp class=”option”>leave</samp></dt> <dd> The command is sent when the current frame timestamp leaves the specified interval. In other words, the command is sent when the previous frame timestamp was in the given interval, and the current is not. </dd> <dt><samp class=”option”>expr</samp></dt> <dd> The command <var class=”var”>ARG</var> is interpreted as expression and result of expression is passed as <var class=”var”>ARG</var>. The expression is evaluated through the eval API and can contain the following constants: <dl class=”table”> <dt><samp class=”option”>POS</samp></dt> <dd> Original position in the file of the frame, or undefined if undefined for the current frame. Deprecated, do not use. </dd> <dt><samp class=”option”>PTS</samp></dt> <dd> The presentation timestamp in input. </dd> <dt><samp class=”option”>N</samp></dt> <dd> The count of the input frame for video or audio, starting from 0. </dd> <dt><samp class=”option”>T</samp></dt> <dd> The time in seconds of the current frame. </dd> <dt><samp class=”option”>TS</samp></dt> <dd> The start time in seconds of the current command interval. </dd> <dt><samp class=”option”>TE</samp></dt> <dd> The end time in seconds of the current command interval. </dd> <dt><samp class=”option”>TI</samp></dt> <dd> The interpolated time of the current command interval, TI = (T - TS) / (TE - TS). </dd> <dt><samp class=”option”>W</samp></dt> <dd> The video frame width. </dd> <dt><samp class=”option”>H</samp></dt> <dd> The video frame height. </dd> </dl>

</dd> </dl>

If <var class=”var”>FLAGS</var> is not specified, a default value of <code class=”code”>[enter]</code> is assumed. <var class=”var”>TARGET</var> specifies the target of the command, usu-

ally the name of the filter class or a specific filter instance name. <var class="var">COMMAND</var> specifies the name of the command for the target filter. <var class="var">ARG</var> is optional and specifies the optional list of argument for the given <var class="var">COMMAND</var>. Between one interval specification and another, whitespaces, or sequences of characters starting with <code class="code">#</code> until the end of line, are ignored and can be used to annotate comments. A simplified BNF description of the commands specification syntax follows: <pre class="example-preformatted"><var class="var">COMMAND_FLAG</var> ::= "enter" | "leave" <var class="var">COMMAND_FLAGS</var> ::= <var class="var">COMMAND_FLAG</var> [(+|"|")<var class="var">COMMAND_FLAG</var>] <var class="var">COMMAND</var> ::= ["[" <var class="var">COMMAND_FLAGS</var> "]"] <var class="var">TARGET</var> <var class="var">COMMAND</var> [<var class="var">ARG</var>] <var class="var">COMMANDS</var> ::= <var class="var">COMMAND</var> [,<var class="var">COMMANDS</var>] <var class="var">INTERVAL</var> ::= <var class="var">START</var>[-<var class="var">END</var>] <var class="var">COMMANDS</var> <var class="var">INTERVALS</var> ::= <var class="var">INTERVAL</var>[;<var class="var">INTERVALS</var>] </pre>

 <h4 class="subsection">48.18.2 Examples# TOC</h4>

 <h3 class=”section”>48.32 spectrumsynth# TOC</h3>

Synthesize audio from 2 input video spectrums, first input stream represents magnitude across time and second represents phase across time. The filter will transform from frequency domain as displayed in videos back to time domain as presented in audio output.
This filter is primarily created for reversing processed showspectrum filter outputs, but can synthesize sound from other spectrograms too. But in such case results are going to be poor if the phase data is not available, because in such cases phase data need to be recreated, usually it’s just recreated from random noise. For best results use gray only output (<code class=”code”>channel</code> color mode in showspectrum filter) and <code class=”code”>log</code> scale for magnitude video and <code class=”code”>lin</code> scale for phase video. To produce phase, for 2nd video, use <code class=”code”>data</code> option. Inputs

videos should generally use <code class="code">fullframe</code> slide mode as that saves resources needed for decoding video. The filter accepts the following options: <dl class="table"> <dt><samp class="option">sample_rate</samp></dt> <dd> Specify sample rate of output audio, the sample rate of audio from which spectrum was generated may differ. </dd> <dt><samp class="option">channels</samp></dt> <dd> Set number of channels represented in input video spectrums. </dd> <dt><samp class="option">scale</samp></dt> <dd> Set scale which was used when generating magnitude input spectrum. Can be <code class="code">lin</code> or <code class="code">log</code>. Default is <code class="code">log</code>. </dd> <dt><samp class="option">slide</samp></dt> <dd> Set slide which was used when generating inputs spectrums. Can be <code class="code">replace</code>, <code class="code">scroll</code>, <code class="code">fullframe</code> or <code class="code">rscroll</code>. Default is <code class="code">fullframe</code>. </dd> <dt><samp class="option">win_func</samp></dt> <dd> Set window function used for resynthesis. </dd> <dt><samp class="option">overlap</samp></dt> <dd> Set window overlap. In range <code class="code">[0, 1]</code>. Default is <code class="code">1</code>, which means optimal overlap for selected window function will be picked. </dd> <dt><samp class="option">orientation</samp></dt> <dd> Set orientation of input videos. Can be <code class="code">vertical</code> or <code class="code">horizontal</code>. Default is <code class="code">vertical</code>. </dd> </dl>

 <h4 class="subsection">48.32.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> First create magnitude and phase videos from audio, assuming audio is stereo with 44100 sample rate, then resynthesize videos back to audio with spectrumsynth: <pre class="example-preformatted">ffmpeg -i input.flac -lavfi showspectrum=mode=separate:scale=log:overlap=0.875:color=channel:slide=fullframe:data=magnitude -an -c:v rawvideo magnitude.nut ffmpeg -i input.flac -lavfi showspectrum=mode=separate:scale=lin:overlap=0.875:color=channel:slide=fullframe:data=phase -an -c:v rawvideo phase.nut ffmpeg -i magnitude.nut -i phase.nut -lavfi spectrumsynth=channels=2:sample_rate=44100:win_func=hann:overlap=0.875:slide=fullframe output.flac </pre>

<ul class="itemize mark-bullet"> Create two separate outputs from the same input: <pre class="example-preformatted">[in] split [out0][out1] </pre>

To create 3 or more outputs, you need to specify the number of outputs, like in: <pre class="example-preformatted">[in] asplit=3 [out0][out1][out2] </pre>

Create two separate outputs from the same input, one cropped and one padded: <pre class="example-preformatted">[in] split [splitout1][splitout2]; [splitout1] crop=100:100:0:0 [cropout]; [splitout2] pad=200:200:100:100 [padout]; </pre>

Create 5 copies of the input audio with <code class="command">ffmpeg</code>:
 <pre class="example-preformatted">ffmpeg -i INPUT -filter_complex asplit=5 OUTPUT </pre>

 <h3 class="section">48.34 zmq, azmq# TOC</h3>

Receive commands sent through a libzmq client, and forward them to filters in the filtergraph. <code class="code">zmq</code> and <code class="code">azmq</code> work as a pass-through filters. <code class="code">zmq</code> must be inserted between two video filters, <code class="code">azmq</code> between two audio filters. Both are capable to send messages to any filter type. To enable these filters you need to install the libzmq library and headers and configure FFmpeg with <code class="code">--enable-libzmq</code>. For more information about libzmq see: http://www.zeromq.org/
The <code class="code">zmq</code> and <code class="code">azmq</code> filters work as a libzmq server, which receives messages sent through a network interface defined by the <samp class="option">bind_address</samp> (or the abbreviation "<samp class="option">b</samp>") option. Default value of this option is <samp class="file">tcp://localhost:5555</samp>. You may want to alter this value to your needs, but do not forget to escape any ’:’ signs (see filtergraph escaping). The received message must be in the form: <pre class="example-preformatted"><var class="var">TARGET</var> <var class="var">COMMAND</var>

[<var class=”var”>ARG</var>] </pre>

<var class=”var”>TARGET</var> specifies the target of the command, usually the name of the filter class or a specific filter instance name. The default filter instance name uses the pattern ‘<samp class=”samp”>Parsed_<filter_name>_<index></samp>’, but you can override this by using the ‘<samp class=”samp”>filter_name@id</samp>’ syntax (see Filtergraph syntax). <var class=”var”>COMMAND</var> specifies the name of the command for the target filter. <var class=”var”>ARG</var> is optional and specifies the optional argument list for the given <var class=”var”>COMMAND</var>. Upon reception, the message is processed and the corresponding command is injected into the filtergraph. Depending on the result, the filter will send a reply to the client, adopting the format: <pre class=”example-preformatted”><var class=”var”>ERROR_CODE</var> <var class=”var”>ERROR_REASON</var> <var class=”var”>MESSAGE</var> </pre>

<var class=”var”>MESSAGE</var> is optional. <h4 class=”subsection”>48.34.1 Examples# TOC</h4>

Look at <samp class=”file”>tools/zmqsend</samp> for an example of a zmq client which can be used to send commands processed by these filters. Consider the following filtergraph generated by <code class=”command”>ffplay</code>. In this example the last overlay filter has an instance name. All other filters will have default instance names.   <pre class=”example-preformatted”>ffplay -dumpgraph 1 -f lavfi " color=s=100x100:c=red [l]; color=s=100x100:c=blue [r]; nullsrc=s=200x100, zmq [bg]; [bg][l] overlay [bg+l]; [bg+l][r] overlay@my=x=100 " </pre>

To change the color of the left side of the video, the following command can be used: <pre class=”example-preformatted”>echo Parsed_color_0 c yellow | tools/zmqsend </pre>

To change the right side: <pre class=”example-preformatted”>echo Parsed_color_1 c pink | tools/zmqsend </pre>

To change the position of the right side: <pre class=”example-preformatted”>echo overlay@my x 150 | tools/zmqsend </pre>

 <h2 class=”chapter”>49 Multimedia Sources# TOC</h2>

Below is a description of the currently available multimedia sources. <h3 class="section">49.1 amovie# TOC</h3>

This is the same as movie source, except it selects an audio stream by default. <h3 class="section">49.2 avsynctest# TOC</h3> Generate an Audio/Video Sync Test. Generated stream periodically shows flash video frame and emits beep in audio. Useful to inspect A/V sync issues. It accepts the following options: <dl class="table"> <dt><samp class="option">size, s</samp></dt> <dd> Set output video size. Default value is <code class="code">hd720</code>. </dd> <dt><samp class="option">framerate, fr</samp></dt> <dd> Set output video frame rate. Default value is <code class="code">30</code>. </dd> <dt><samp class="option">samplerate, sr</samp></dt> <dd> Set output audio sample rate. Default value is <code class="code">44100</code>. </dd> <dt><samp class="option">amplitude, a</samp></dt> <dd> Set output audio beep amplitude. Default value is <code class="code">0.7</code>. </dd> <dt><samp class="option">period, p</samp></dt> <dd> Set output audio beep period in seconds. Default value is <code class="code">3</code>. </dd> <dt><samp class="option">delay, dl</samp></dt> <dd> Set output video flash delay in number of frames. Default value is <code class="code">0</code>. </dd> <dt><samp class="option">cycle, c</samp></dt> <dd> Enable cycling of video delays, by default is disabled. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Set stream output duration. By default duration is unlimited. </dd> <dt><samp class="option">fg, bg, ag</samp></dt> <dd> Set foreground/background/additional color. </dd> </dl>

 <h4 class="subsection">49.2.1 Commands# TOC</h4>

This source supports the some above options as commands. <h3 class="section">49.3 movie# TOC</h3>

Read audio and/or video stream(s) from a movie container. It accepts the following parameters: <dl class="table"> <dt><samp

class=”option”>filename</samp></dt> <dd> The name of the resource to read (not necessarily a file; it can also be a device or a stream accessed through some protocol). </dd> <dt><samp class=”option”>format_name, f</samp></dt> <dd> Specifies the format assumed for the movie to read, and can be either the name of a container or an input device. If not specified, the format is guessed from <var class=”var”>movie_name</var> or by probing. </dd> <dt><samp class=”option”>seek_point, sp</samp></dt> <dd> Specifies the seek point in seconds. The frames will be output starting from this seek point. The parameter is evaluated with <code class=”code”>av_strtod</code>, so the numerical value may be suffixed by an IS postfix. The default value is "0". </dd> <dt><samp class=”option”>streams, s</samp></dt> <dd> Specifies the streams to read. Several streams can be specified, separated by "+". The source will then have as many outputs, in the same order. The syntax is explained in the <a data-manual=”ffmpeg” href=”./ffmpeg.html#Stream-specifiers”>"Stream specifiers" section in the ffmpeg manual. Two special names, "dv" and "da" specify respectively the default (best suited) video and audio stream. Default is "dv", or "da" if the filter is called as "amovie". </dd> <dt><samp class=”option”>stream_index, si</samp></dt> <dd> Specifies the index of the video stream to read. If the value is -1, the most suitable video stream will be automatically selected. The default value is "-1". Deprecated. If the filter is called "amovie", it will select audio instead of video. </dd> <dt><samp class=”option”>loop</samp></dt> <dd> Specifies how many times to read the stream in sequence. If the value is 0, the stream will be looped infinitely. Default value is "1". Note that when the movie is looped the source timestamps are not changed, so it will generate non monotonically increasing timestamps. </dd> <dt><samp class=”option”>discontinuity</samp></dt> <dd> Specifies the time difference between frames above which the point is considered a timestamp discontinuity which is removed by adjusting the later timestamps. </dd> <dt><samp class=”option”>dec_threads</samp></dt> <dd> Specifies the number of threads for decoding </dd> <dt><samp class=”option”>format_opts</samp></dt> <dd> Specify format options for the opened file. Format options can be specified as a list of <var class=”var”>key</var>=<var class=”var”>value</var> pairs separated by ’:’. The following example shows how to add protocol_whitelist and protocol_blacklist options: <pre class=”example-preformatted”>ffplay -f lavfi "movie=filename='1.sdp':format_opts='protocol_whitelist=file,rtp,udp\:protocol_blacklist=http'&quo
</pre> </dd> </dl>

It allows overlaying a second video on top of the main input of a filtergraph, as shown in this graph: <pre class=”example-preformatted”>input ----------> deltapts0 --> overlay

--> output ^ | movie --> scale--> deltapts1 -------+ </pre> <h4 class="subsection">49.3.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Skip 3.2 seconds from the start of the AVI file in.avi, and overlay it on top of the input labelled "in": <pre class="example-preformatted">movie=in.avi:seek_point=3.2, scale=180:-1, setpts=PTS-STARTPTS [over]; [in] setpts=PTS-STARTPTS [main]; [main][over] overlay=16:16 [out] </pre>

Read from a video4linux2 device, and overlay it on top of the input labelled "in": <pre class="example-preformatted">movie=/dev/video0:f=video4linux2, scale=180:-1, setpts=PTS-STARTPTS [over]; [in] setpts=PTS-STARTPTS [main]; [main][over] overlay=16:16 [out] </pre>

Read the first video stream and the audio stream with id 0x81 from dvd.vob; the video is connected to the pad named "video" and the audio is connected to the pad named "audio": <pre class="example-preformatted">movie=dvd.vob:s=v:0+#0x81 [video] [audio] </pre>

 <h4 class="subsection">49.3.2 Commands# TOC</h4>

Both movie and amovie support the following commands: <dl class="table"> <dt><samp class="option">seek</samp></dt> <dd> Perform seek using "av_seek_frame". The syntax is: seek <var class="var">stream_index</var>|<var class="var">timestamp</var>|<var class="var">flags</var> <ul class="itemize mark-bullet"> <var class="var">stream_index</var>: If stream_index is -1, a default stream is selected, and <var class="var">timestamp</var> is automatically converted from AV_TIME_BASE units to the stream specific time_base. <var class="var">timestamp</var>: Timestamp in AVStream.time_base units or, if no stream is specified, in AV_TIME_BASE units. <var class="var">flags</var>: Flags which select direction and seeking mode.

</dd> <dt><samp class="option">get_duration</samp></dt> <dd> Get movie duration in AV_TIME_BASE units. </dd> </dl>

 <h2 class="chapter">50 External libraries# TOC</h2>

FFmpeg can be hooked up with a number of external libraries to add support for more formats. None of them are used by default, their use has to be explicitly requested by passing the appropriate flags to <code class=”command”>./configure</code>. <h3 class=”section”>50.1 Alliance for Open Media (AOM)# TOC</h3>

FFmpeg can make use of the AOM library for AV1 decoding and encoding. Go to http://aomedia.org/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libaom</code> to configure to enable it. <h3 class=”section”>50.2 ARM ASTC Encoder# TOC</h3>

FFmpeg can make use of the Arm ASTC Encoder library for ASTC image compression and decompression in the <code class=”code”>libastcenc</code> encoder and decoder. Go to https://github.com/ARM-software/astc-encoder to obtain the sources. Version 5.4 or newer is required, because the wrappers use the four-argument <code class=”code”>astcenc_context_alloc()</code> interface introduced in that release. The upstream build does not install the public header, and the library file name depends on the configured SIMD and linkage variants, so install the pieces manually in a layout that configure can detect: the header as <code class=”code”>astcenc/astcenc.h</code> and a library that can be linked with <code class=”code”>-lastcenc</code>. Keep the library’s own file name, which is the SONAME recorded in the binary, and provide the plain name as an alias: <pre class=”example-preformatted”>cmake -S . -B build -DCMAKE_BUILD_TYPE=Release -DASTCENC_SHAREDLIB=ON cmake --build build install -Dm644 Source/astcenc.h /usr/local/include/astcenc/astcenc.h install -Dm755 build/Source/libastcenc-native-shared.so \ /usr/local/lib/libastcenc-native-shared.so ln -sf libastcenc-native-shared.so /usr/local/lib/libastcenc.so </pre>

Use the platform’s shared library suffix, and adjust the built library name for other variants (for example <samp class=”file”>libastcenc-neon-shared.so</samp> or a static <samp class=”file”>libastcenc.a</samp>), or pass <code class=”code”>--extra-cflags</code> and <code class=”code”>--extra-ldflags</code> to configure if the files are installed elsewhere. Installing only under the plain name breaks linking at run time, and the installation directory has to be in the runtime loader’s search

path. On big-endian systems, also pass <code class="code">-DASTCENC_ISA_NONE=ON</code> and <code class="code">-DASTCENC_BIG_ENDIAN=ON</code> to CMake. For this variant, install <samp class="file">libastcenc-none-shared.so</samp> under its own name and provide <samp class="file">libastcenc.so</samp> as an alias, as in the example above. The library is licensed under Apache-2.0, which requires version 3 of the (L)GPL, so pass <code class="code">--enable-version3</code> and <code class="code">--enable-libastcenc</code> to configure to enable it. <h3 class="section">50.3 AMD AMF/VCE# TOC</h3>

FFmpeg can use the AMD Advanced Media Framework library for accelerated H.264 and HEVC(only windows) encoding on hardware with Video Coding Engine (VCE). To enable support you must obtain the AMF framework header files(version 1.4.9+) from https://github.com/GPUOpen-LibrariesAndSDKs/AMF.git. Create an <code class="code">AMF/</code> directory in the system include path. Copy the contents of <code class="code">AMF/amf/public/include/</code> into that directory. Then configure FFmpeg with <code class="code">--enable-amf</code>. Initialization of amf encoder occurs in this order: 1) trying to initialize through dx11(only windows) 2) trying to initialize through dx9(only windows) 3) trying to initialize through vulkan To use h.264(AMD VCE) encoder on linux amdgru-pro version 19.20+ and amf-amdgpu-pro package(amdgru-pro contains, but does not install automatically) are required. This driver can be installed using amdgpu-pro-install script in official amd driver archive. <h3 class="section">50.4 AviSynth# TOC</h3>

FFmpeg can read AviSynth scripts as input. To enable support, pass <code class="code">--enable-avisynth</code> to configure after installing the headers provided by AviSynth+. AviSynth+ can be configured to install only the headers by either passing <code class="code">-DHEADERS_ONLY:bool=on</code> to the normal CMake-based build system, or by using the supplied <code class="code">GNUmakefile</code>. For Windows, supported AviSynth variants are AviSynth 2.6 RC1 or higher for 32-bit builds and Avi
r1718 or higher for 32-bit and 64-bit builds. For Linux, macOS, and BSD, the only supported AviSynth variant is AviSynth+, start-

ing with version 3.5.   In 2016, AviSynth+ added support for building with GCC. However, due to the eccentricities of Windows’ calling conventions, 32-bit GCC builds of AviSynth+ are not compatible with typical 32-bit builds of FFmpeg. By default, FFmpeg assumes compatibility with 32-bit MSVC builds of AviSynth+ since that is the most widely-used and entrenched build configuration. Users can override this and enable support for 32-bit GCC builds of AviSynth+ by passing <code class=”code”>-DAVSC_WIN32_GCC32</code> to <code class=”code”>--extra-cflags</code> when configuring FFmpeg. 64-bit builds of FFmpeg are not affected, and can use either MSVC or GCC builds of AviSynth+ without any special flags.   AviSynth(+) is loaded dynamically. Distributors can build FFmpeg with <code class=”code”>--enable-avisynth</code>, and the binaries will work regardless of the end user having AviSynth installed. If/when an end user would like to use AviSynth scripts, then they can install AviSynth(+) and FFmpeg will be able to find and use it to open scripts. <h3 class=”section”>50.5 Chromaprint# TOC</h3>

FFmpeg can make use of the Chromaprint library for generating audio fingerprints. Pass <code class=”code”>--enable-chromaprint</code> to configure to enable it. See https://acoustid.org/chromapri
  <h3 class=”section”>50.6 codec2# TOC</h3>

FFmpeg can make use of the codec2 library for codec2 decoding and encoding. There is currently no native decoder, so libcodec2 must be used for decoding. Go to http://freedv.org/, download "Codec 2 source archive". Build and install using CMake. Debian users can install the libcodec2-dev package instead. Once libcodec2 is installed you can pass <code class=”code”>--enable-libcodec2</code> to configure to enable it. The easiest way to use codec2 is with .c2 files, since they contain the mode information required for decoding. To encode such a file, use a .c2 file extension and give the libcodec2 encoder the -mode option: <code class=”code”>ffmpeg -i input.wav -mode 700C output.c2</code>. Playback is as simple as <code class=”code”>ffplay output.c2</code>. For a list of supported modes, run <code class=”code”>ffmpeg -h encoder=libcodec2</code>. Raw codec2 files are also supported. To make sense of them the mode in use needs to be specified as a format option: <code class=”code”>ffmpeg -f codec2raw -mode 1300 -i input.raw output.wav</code>. <h3 class=”section”>50.7 dav1d# <a class=”anchor hidden-xs”href=”#toc-dav1d”

Emu<a class=”anchor hidden-xs” href=”#Game-
Music-Emu” aria-hidden=”true”># <a class=”anchor hidden-
xs”href=”#toc-Game-Music-Emu” aria-hidden=”true”>TOC</h3>

FFmpeg can make use of the Game Music Emu library to read audio
from supported video game music file formats. Pass <code class=”code”>-
-enable-libgme</code> to configure to enable it. See <a class=”url”
href=”https://bitbucket.org/mpyne/game-music-emu/overview”>https://bitbucket.org/mpyne/game-
music-emu/overview.
<h3 class=”section”>50.11 Intel QuickSync Video<span class=”pull-
right”><a class=”anchor hidden-xs” href=”#Intel-QuickSync-Video”
aria-hidden=”true”># <a class=”anchor hidden-xs”href=”#toc-Intel-
QuickSync-Video” aria-hidden=”true”>TOC</h3>

FFmpeg can use Intel QuickSync Video (QSV) for accelerated decoding
and encoding of multiple codecs. To use QSV, FFmpeg must be linked
against the <code class=”code”>libmfx</code> dispatcher, which loads
the actual decoding libraries. The dispatcher is open source
and can be downloaded from <a class=”url” href=”https://github.com/lu-
zero/mfx_dispatch.git”>https://github.com/lu-zero/mfx_dispatch.git.

FFmpeg needs to be configured with the <code class="code">--enable-libmfx</code> option and <code class="code">pkg-config</code> needs to be able to locate the dispatcher’s <code class="code">.pc</code> files. <h3 class="section">50.12 Kvazaar# TOC</h3>

FFmpeg can make use of the Kvazaar library for HEVC encoding. Go to <a class="url" href="https://github.com/ultravideo/kvazaar">https://github.com/ultravideo/kvaz and follow the instructions for installing the library. Then pass <code class="code">--enable-libkvazaar</code> to configure to enable it. <h3 class="section">50.13 LAME# TOC</h3>

FFmpeg can make use of the LAME library for MP3 encoding. Go to http://lame.sourceforge.net/ and follow the instructions for installing the library. Then pass <code class="code">--enable-libmp3lame</code> to configure to enable it. <h3 class="section">50.14 LCEVCdec# TOC</h3>

FFmpeg can make use of the liblcevc_dec library for LCEVC enhancement layer decoding on supported bitstreams. Go to https://github.com/v-novaltd/LCEVCdec and follow the instructions for installing the library. Then pass <code class="code">--enable-liblcevc-dec</code> to configure to enable it.   LCEVCdec is under the BSD-3-Clause-Clear License. <h3 class="section">50.15 libilbc# TOC</h3>

iLBC is a narrowband speech codec that has been made freely available by Google as part of the WebRTC project. libilbc is a packaging friendly copy of the iLBC codec. FFmpeg can make use of the libilbc library for iLBC decoding and encoding. Go to https://github.com/TimothyGu/libilbc and follow the instructions for installing the library. Then pass <code class="code">--enable-libilbc</code> to configure to enable it. <h3 class="section">50.16 libjxl# TOC</h3>

JPEG XL is an image format intended to fully replace legacy JPEG for an extended period of life. See https://jpegxl.info/ for more information, and see <a class="url" href="https://github.com/libjxl/libjxl">https://github.com/libj for the library source. You can pass <code class="code">--enable-libjxl</code> to configure in order enable the libjxl wrapper. <h3 class="section">50.17 libvpx# TOC</h3>

FFmpeg can make use of the libvpx library for VP8/VP9 decoding and encoding. Go to <a class="url" href="http://www.webmproject.org/">http://www.webmproject.org and follow the instructions for installing the library. Then pass <code class="code">--enable-libvpx</code> to configure to enable it. <h3 class="section">50.18 ModPlug# TOC</h3>

FFmpeg can make use of this library, originating in Modplug-XMMS, to read from MOD-like music files. See <a class="url" href="https://github.com/Konstanty/libmodplug">https:/ Pass <code class="code">--enable-libmodplug</code> to configure to enable it. <h3 class="section">50.19 ONNX Runtime# TOC</h3>

FFmpeg can make use of the ONNX Runtime library as a backend for DNN based filters. Go to https://onnxruntime.ai/ and follow the instructions for installing the library. Pre-built packages are available for various platforms. Configure FFmpeg with ONNX Runtime support: <pre class="example-preformatted">./configure \ --enable-libonnxruntime \ --extra-cflags="-I/path/to/onnxruntime/include" \ --extra-ldflags="-L/path/to/onnxruntime/lib" </pre>

On ELF-based systems (Linux, BSD) you may also want to embed the library search path so that the installed <samp class="file">ffmpeg</samp> binary finds the shared library at run time without setting <code class="env">LD_LIBRARY_PATH</code>:   <pre class="example-preformatted">./configure \ --enable-libonnxruntime \ --extra-cflags="-I/path/to/onnxruntime/include" \ --extra-ldflags="-L/path/to/onnxruntime/lib -Wl,-rpath,/path/to/onnxruntime/lib" </pre>

The <code class="code">-Wl,-rpath</code> flag is ELF-specific and should be omitted on other platforms (Windows, macOS). For MinGW GCC builds, add the <code class="code">-D_stdcall=___stdcall</code>

flag for compatibility with ONNX Runtime headers. <h3 class="section">50.20 OpenCORE, VisualOn, and Fraunhofer libraries# TOC</h3>

Spun off Google Android sources, OpenCore, VisualOn and Fraunhofer libraries provide encoders for a number of audio codecs.   OpenCORE and VisualOn libraries are under the Apache License 2.0 (see http://www.apache.org/licenses/LICENSE-2.0 for details), which is incompatible to the LGPL version 2.1 and GPL version 2. You have to upgrade FFmpeg’s license to LGPL version 3 (or if you have enabled GPL components, GPL version 3) by passing <code class="code">--enable-version3</code> to configure in order to use it. The license of the Fraunhofer AAC library is incompatible with the GPL. Therefore, for GPL builds, you have to pass <code class="code">--enable-nonfree</code> to configure in order to use it. To the best of our knowledge, it is compatible with the LGPL. <h4 class="subsection">50.20.1 OpenCORE AMR# TOC</h4>

FFmpeg can make use of the OpenCORE libraries for AMR-NB decoding/encoding and AMR-WB decoding. Go to http://sourceforge.net/projects/opencore-amr/ and follow the instructions for installing the libraries. Then pass <code class="code">--enable-libopencore-amrnb</code> and/or <code class="code">--enable-libopencore-amrwb</code> to configure to enable them. <h4 class="subsection">50.20.2 VisualOn AMR-WB encoder library# TOC</h4>

FFmpeg can make use of the VisualOn AMR-WBenc library for AMR-WB encoding. Go to http://sourceforge.net/projects/opencore-amr/ and follow the instructions for installing the library. Then pass <code class="code">--enable-libvo-amrwbenc</code> to configure to enable it. <h4 class="subsection">50.20.3 Fraunhofer AAC library#

TOC</h4>

FFmpeg can make use of the Fraunhofer AAC library for AAC decoding & encoding. Go to http://sourceforge.net/projects/opencore-amr/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libfdk-aac</code> to configure to enable it. <h4 class=”subsection”>50.20.4 Fraunhofer xHE-AAC library# TOC</h4>

FFmpeg can make use of the Fraunhofer xHE-AAC library for xHE-AAC encoding. Go to http://sourceforge.net/projects/opencore-amr/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libfdk-xhe-aac</code> to configure to enable it. <h4 class=”subsection”>50.20.5 Fraunhofer MPEG-H 3D Audio decoder library# TOC</h4>

FFmpeg can make use of the Fraunhofer MPEG-H decoder library for MPEG-H 3DA decoding. Go to https://github.com/Fraunhofer-IIS/mpeghdec and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libmpeghdec --enable-nonfree</code> to configure to enable it. <h4 class=”subsection”>50.20.6 LC3 library# TOC</h4>

FFmpeg can make use of the Google LC3 library for LC3 decoding & encoding. Go to <a class=”url” href=”https://github.com/google/liblc3/”>https://github.com/go and follow the instructions for installing the library. Then pass <code class=”code”>--enable-liblc3</code> to configure to enable it. <h3 class=”section”>50.21 OpenH264# TOC</h3>

FFmpeg can make use of the OpenH264 library for H.264 decoding and encoding. Go to http://www.openh264.org/ and follow the instructions for installing the library. Then pass <code

class=”code”>--enable-libopenh264</code> to configure to enable it. For decoding, this library is much more limited than the built-in decoder in libavcodec; currently, this library lacks support for decoding B-frames and some other main/high profile features. (It currently only supports constrained baseline profile and CABAC.) Using it is mostly useful for testing and for taking advantage of Cisco’s patent portfolio license (http://www.openh264.org/BINARY_LICENSE.
  <h3 class=”section”>50.22 Open-JPEG# TOC</h3>

FFmpeg can use the OpenJPEG libraries for decoding/encoding J2K videos. Go to http://www.openjpeg.org/ to get the libraries and follow the installation instructions. To enable using OpenJPEG in FFmpeg, pass <code class=”code”>--enable-libopenjpeg</code> to <samp class=”file”>./configure</samp>. <h3 class=”section”>50.23 rav1e# TOC</h3>

FFmpeg can make use of rav1e (Rust AV1 Encoder) via its C bindings to encode videos. Go to https://github.com/xiph/rav1e/< and follow the instructions to build the C library. To enable using rav1e in FFmpeg, pass <code class=”code”>--enable-librav1e</code> to <samp class=”file”>./configure</samp>. <h3 class=”section”>50.24 SVT-AV1# TOC</h3>

FFmpeg can make use of the Scalable Video Technology for AV1 library for AV1 encoding. Go to https://gitlab.com/AOMediaCodec/SVT-AV1/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libsvtav1</code> to configure to enable it. <h3 class=”section”>50.25 SVT-JPEG-XS# TOC</h3>

FFmpeg can make use of the Scalable Video Technology for JPEG-XS library for JPEG-XS decoding and encoding. Go to https://github.com/OpenVisualCloud/SVT-JPEG-XS and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libsvtjpegxs</code> to configure to enable it. <h3 class=”section”>50.26 TwoLAME<a class=”anchor hidden-xs” href=”#TwoLAME” aria-

hidden=”true”># TOC</h3>

FFmpeg can make use of the TwoLAME library for MP2 encoding. Go to http://www.twolame.org/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libtwolame</code> to configure to enable it. <h3 class=”section”>50.27 VapourSynth# TOC</h3>

FFmpeg can read VapourSynth scripts as input. To enable support, pass <code class=”code”>--enable-vapoursynth</code> to configure. Vapoursynth is detected via <code class=”code”>pkg-config</code>. Versions 42 or greater supported. See http://www.vapoursynth.com/. Due to security concerns, Vapoursynth scripts will not be autodetected so the input format has to be forced. For ff* CLI tools, add <code class=”code”>-f vapoursynth</code> before the input <code class=”code”>-i yourscript.vpy</code>. <h3 class=”section”>50.28 x264# TOC</h3>

FFmpeg can make use of the x264 library for H.264 encoding. Go to http://www.videolan.org/d and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libx264</code> to configure to enable it.   x264 is under the GNU Public License Version 2 or later (see http://www.gnu.org/licenses/old-licenses/gpl-2.0.html for details), you must upgrade FFmpeg’s license to GPL in order to use it. <h3 class=”section”>50.29 x265# TOC</h3>

FFmpeg can make use of the x265 library for HEVC encoding. Go to http://x265.org/developers.html and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libx265</code> to configure to enable it.   x265 is under the GNU Public License Version 2 or later (see http://www.gnu.org/licenses/old-licenses/gpl-2.0.html for details), you must upgrade FFmpeg’s license to GPL in order to use it. <h3 class=”section”>50.30 xavs# <a class=”anchor hidden-xs”href=”#toc-xavs”

aria-hidden=”true”>TOC</h3>

FFmpeg can make use of the xavs library for AVS encoding. Go to http://xavs.sf.net/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libxavs</code> to configure to enable it. <h3 class=”section”>50.31 xavs2# TOC</h3>

FFmpeg can make use of the xavs2 library for AVS2-P2/IEEE1857.4 video encoding. Go to https://github.com/pku and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libxavs2</code> to configure to enable it.   libxavs2 is under the GNU Public License Version 2 or later (see http://www.gnu.org/licenses/old-licenses/gpl-2.0.html for details), you must upgrade FFmpeg’s license to GPL in order to use it. <h3 class=”section”>50.32 eXtra-fast Essential Video Encoder (XEVE)# TOC</h3>

FFmpeg can make use of the XEVE library for EVC video encoding. Go to https://github.com/mpeg5/xeve and follow the instructions for installing the XEVE library. Then pass <code class=”code”>--enable-libxeve</code> to configure to enable it. <h3 class=”section”>50.33 eXtra-fast Essential Video Decoder (XEVD)# TOC</h3>

FFmpeg can make use of the XEVD library for EVC video decoding. Go to https://github.com/mpeg5/xevd and follow the instructions for installing the XEVD library. Then pass <code class=”code”>--enable-libxevd</code> to configure to enable it. <h3 class=”section”>50.34 ZVBI# TOC</h3>

ZVBI is a VBI decoding library which can be used by FFmpeg to decode DVB teletext pages and DVB teletext subtitles. Go to <a

class=”url” href=”http://sourceforge.net/projects/zapping/”>http://sourceforge.net/projects/zapping/ and follow the instructions for installing the library. Then pass <code class=”code”>--enable-libzvbi</code> to configure to enable it. <h2 class=”chapter”>51 Supported File Formats, Codecs or Features# TOC</h2>

You can use the <code class=”code”>-formats</code> and <code class=”code”>-codecs</code> options to have an exhaustive list. <h3 class=”section”>51.1 File Formats# TOC</h3>

FFmpeg supports the following file formats through the <code class=”code”>libavformat</code>

library:

<table class=”multitable”>

<tbody><tr><td width=”40%”>Name</td><td width=”10%”>Encoding</td><td width=”10%”>Decoding</td><td width=”40%”>Comments</td></tr>

 <h2 class=”chapter”>1 Description# TOC</h2>

This document describes the bitstream filters provided by the libavcodec library. A bitstream filter operates on the encoded stream data, and performs bitstream level modifications without performing decoding.

 <h2 class=”chapter”>2 Bitstream Filters# TOC</h2>

When you configure your FFmpeg build, all the supported bitstream filters are enabled by default. You can list all available ones using the configure option <code class=”code”>--list-bsfs</code>. You can disable all the bitstream filters using the configure option <code class=”code”>--disable-bsfs</code>, and selectively enable any bitstream filter using the option <code class=”code”>--enable-bsf=BSF</code>, or you can disable a particular bitstream filter using the option <code class=”code”>--disable-bsf=BSF</code>. The option <code class=”code”>-bsfs</code> of the ff* tools will display the list of all the supported bitstream filters included in your build. The ff* tools have a -bsf option applied per stream, taking a comma-separated list of filters, whose parameters follow the filter name after a ’=’.   <pre class=”example-preformatted”>ffmpeg -i INPUT -c:v copy -bsf:v filter1[=opt1=str1:opt2=str2][,filter2] OUTPUT </pre>

Below is a description of the currently available bitstream filters, with their parameters, if any. <h3 class=”section”>2.1 aac_adtstoasc# TOC</h3>

Convert MPEG-2/4 AAC ADTS to an MPEG-4 Audio Specific Configuration bitstream. This filter creates an MPEG-4 AudioSpecificConfig

from an MPEG-2/4 ADTS header and removes the ADTS header. This filter is required for example when copying an AAC stream from a raw ADTS AAC or an MPEG-TS container to MP4A-LATM, to an FLV file, or to MOV/MP4 files and related formats such as 3GP or M4A. Please note that it is auto-inserted for MP4A-LATM and MOV/MP4 and related formats. <h3 class="section">2.2 av1_metadata# TOC</h3>

Modify metadata embedded in an AV1 stream. <dl class="table"> <dt><samp class="option">td</samp></dt> <dd> Insert or remove temporal delimiter OBUs in all temporal units of the stream. <dl class="table"> <dt>‘<samp class="samp">insert</samp>’</dt> <dd> Insert a TD at the beginning of every TU which does not already have one. </dd> <dt>‘<samp class="samp">remove</samp>’</dt> <dd> Remove the TD from the beginning of every TU which has one. </dd> </dl>

</dd> <dt><samp class="option">color_primaries</samp></dt> <dt><samp class="option">transfer_characteristics</samp></dt> <dt><samp class="option">matrix_coefficients</samp></dt> <dd> Set the color description fields in the stream (see AV1 section 6.4.2). </dd> <dt><samp class="option">color_range</samp></dt> <dd> Set the color range in the stream (see AV1 section 6.4.2; note that this cannot be set for streams using BT.709 primaries, sRGB transfer characteristic and identity (RGB) matrix coefficients). <dl class="table"> <dt>‘<samp class="samp">tv</samp>’</dt> <dd> Limited range. </dd> <dt>‘<samp class="samp">pc</samp>’</dt> <dd> Full range. </dd> </dl>

 <h3 class=”section”>2.11 extract_extradata# TOC</h3>

Extract the in-band extradata. Certain codecs allow the long-term headers (e.g. MPEG-2 sequence headers, or H.264/HEVC (VPS/)SPS/PPS) to be transmitted either "in-band" (i.e. as a part of the bitstream containing the coded frames) or "out of band" (e.g. on the container level). This latter form is called "extradata" in FFmpeg terminology. This bitstream filter detects the in-band headers and makes them available as extradata. <dl class=”table”> <dt><samp class=”option”>remove</samp></dt> <dd> When this option is enabled, the long-term headers are removed from the bitstream after extraction. </dd> </dl>

 <h3 class=”section”>2.12 filter_units# TOC</h3>

Remove units with types in or not in a given set from the stream. <dl class=”table”> <dt><samp class=”option”>pass_types</samp></dt> <dd> List of unit types or ranges of unit types to pass through while removing all others. This is specified as a ’|’-separated list of unit type values or ranges of values with ’-’. </dd> <dt><samp class=”option”>remove_types</samp></dt> <dd> Identical to <samp class=”option”>pass_types</samp>, except the units in the given set removed

and all others passed through. </dd> </dl>

The types used by pass_types and remove_types correspond to NAL unit types (nal_unit_type) in H.264, HEVC and H.266 (see Table 7-1 in the H.264 and HEVC specifications or Table 5 in the H.266 specification), to marker values for JPEG (without 0xFF prefix) and to start codes without start code prefix (i.e. the byte following the 0x000001) for MPEG-2. For VP8 and VP9, every unit has type zero. Extradata is unchanged by this transformation, but note that if the stream contains inline parameter sets then the output may be unusable if they are removed. For example, to remove all non-VCL NAL units from an H.264 stream: <pre class="example-preformatted">ffmpeg -i INPUT -c:v copy -bsf:v 'filter_units=pass_types=1-5' OUTPUT </pre>

To remove all AUDs, SEI and filler from an H.265 stream: <pre class="example-preformatted">ffmpeg -i INPUT -c:v copy -bsf:v 'filter_units=remove_types=35|38-40' OUTPUT </pre>

To remove all user data from a MPEG-2 stream, including Closed Captions: <pre class="example-preformatted">ffmpeg -i INPUT -c:v copy -bsf:v 'filter_units=remove_types=178' OUTPUT </pre>

To remove all SEI from a H264 stream, including Closed Captions: <pre class="example-preformatted">ffmpeg -i INPUT -c:v copy -bsf:v 'filter_units=remove_types=6' OUTPUT </pre>

To remove all prefix and suffix SEI from a HEVC stream, including Closed Captions and dynamic HDR: <pre class="example-preformatted">ffmpeg -i INPUT -c:v copy -bsf:v 'filter_units=remove_types=39|40' OUTPUT </pre>

Convert an H.264 bitstream from length prefixed mode to start code

prefixed mode (as defined in the Annex B of the ITU-T H.264 specification). This is required by some streaming formats, typically the MPEG-2 transport stream format (muxer <code class="code">mpegts</code>). For example to remux an MP4 file containing an H.264 stream to mpegts format with <code class="command">ffmpeg</code>, you can use the command: <pre class="example-preformatted">ffmpeg -i INPUT.mp4 -codec copy -bsf:v h264_mp4toannexb OUTPUT.ts </pre>

Please note that this filter is auto-inserted for MPEG-TS (muxer <code class="code">mpegts</code>) and raw H.264 (muxer <code class="code">h264</code>) output formats. <h3 class="section">2.16 h264_redundant_pps# TOC</h3>

This applies a specific fixup to some Blu-ray BDMV H264 streams which contain redundant PPSs. The PPSs modify irrelevant parameters of the stream, confusing other transformations which require the correct extradata. The encoder used on these impacted streams adds extra PPSs throughout the stream, varying the initial QP and whether weighted prediction was enabled. This causes issues after copying the stream into a global header container, as the starting PPS is not suitable for the rest of the stream. One side effect, for example, is seeking will return garbled output until a new PPS appears. This BSF removes the extra PPSs and rewrites the slice headers such that the stream uses a single leading PPS in the global header, which resolves the issue. <h3 class="section">2.17 hevc_metadata# TOC</h3>

Please note that this filter is auto-inserted for MPEG-TS (muxer <code class=”code”>mpegts</code>) and raw HEVC/H.265 (muxer <code class=”code”>h265</code> or <code class=”code”>hevc</code>) output

formats. <h3 class="section">2.19 imxdump# TOC</h3>

Modifies the bitstream to fit in MOV and to be usable by the Final Cut Pro decoder. This filter only applies to the mpeg2video codec, and is likely not needed for Final Cut Pro 7 and newer with the appropriate <samp class="option">-tag:v</samp>. For example, to remux 30 MB/sec NTSC IMX to MOV: <pre class="example-preformatted">ffmpeg -i input.mxf -c copy -bsf:v imxdump -tag:v mx3n output.mov </pre>

 <h3 class="section">2.20 jpegapp# TOC</h3>

Inject JPEG APP0..APP15 segments from a length-prefixed sidecar into each MJPEG packet, after SOI. The sidecar is a sequence of records, one per encoded JPEG, in encode order: <pre class="example-preformatted">u32be length u8 payload[length] </pre>

<var class="var">length</var> does not include the 4-byte prefix and must not exceed 16 MiB. A zero <var class="var">length</var> leaves that packet unchanged. A non-empty payload must be a concatenation of complete APP segments (<code class="code">FF En</code> plus the 16-bit length that includes those two length bytes). If the payload starts with APP0 and the packet has an APP0 marker in the two bytes immediately following SOI, that APP0 segment is dropped. APP0 segments preceded by fill bytes or another segment are retained. An APP1-only payload keeps the encoder APP0: SOI, APP1, APP0, DQT, ... The filter requires <samp class="option">sidecar</samp>. Extra unused sidecar bytes are ignored; a packet without a matching record is an error. Records follow packets in arrival order. Flushing the filter does not rewind the sidecar, so a reused context needs a sidecar positioned for the packets it will see next. A sidecar read or validation error prevents further record consumption by that filter context. To resume, create a new context with a sidecar matching the remaining packets. Flushing does not clear this error.   <pre class="example-preformatted">ffmpeg -i in.mp4 -c:v mjpeg -bsf:v jpegapp=sidecar=00000004DEADBEEF frame_%d.jpg </pre>

 <h3 class="section">2.21 mjpeg2jpeg# TOC</h3>

Convert MJPEG/AVI1 packets to full JPEG/JFIF packets.

MJPEG is a video codec wherein each video frame is essentially a JPEG image. The individual frames can be extracted without loss, e.g. by   <pre class=”example-preformatted”>ffmpeg -i ../some_mjpeg.avi -c:v copy frames_%d.jpg </pre>

Unfortunately, these chunks are incomplete JPEG images, because they lack the DHT segment required for decoding. Quoting from <a class=”url” href=”http://www.digitalpreservation.gov/formats/fdd/fdd000063.shtml”>http://www.digitalpreservation.go
 Avery Lee, writing in the rec.video.desktop newsgroup in 2001, commented that "MJPEG, or at least the MJPEG in AVIs having the MJPG fourcc, is restricted JPEG with a fixed – and *omitted* – Huffman table. The JPEG must be YCbCr colorspace, it must be 4:2:2, and it must use basic Huffman encoding, not arithmetic or progressive. . . . You can indeed extract the MJPEG frames and decode them with a regular JPEG decoder, but you have to prepend the DHT segment to them, or else the decoder won’t have any idea how to decompress the data. The exact table necessary is given in the OpenDML spec." This bitstream filter patches the header of frames extracted from an MJPEG stream (carrying the AVI1 header ID and lacking a DHT segment) to produce fully qualified JPEG images.   <pre class=”example-preformatted”>ffmpeg -i mjpeg-movie.avi -c:v copy -bsf:v mjpeg2jpeg frame_%d.jpg exiftran -i -9 frame*.jpg ffmpeg -i frame_%d.jpg -c:v copy rotated.avi </pre>

Extract a representable text file from MOV subtitles, stripping the metadata header from each subtitle packet. See also the text2movsub filter. <h3 class=”section”>2.24 mpeg2_metadata# TOC</h3>

Modify metadata embedded in an MPEG-2 stream. <dl class=”table”> <dt><samp class=”option”>display_aspect_ratio</samp></dt> <dd> Set the display aspect ratio in the stream. The following fixed values are supported: <dl class=”table”> <dt><samp

class=”option”>4/3</samp></dt> <dt><samp class=”option”>16/9</samp></dt> <dt><samp class=”option”>221/100</samp></dt> </dl> Any other value will result in square pixels being signalled instead (see H.262 section 6.3.3 and table 6-3). </dd> <dt><samp class=”option”>frame_rate</samp></dt> <dd> Set the frame rate in the stream. This is constructed from a table of known values combined with a small multiplier and divisor - if the supplied value is not exactly representable, the nearest representable value will be used instead (see H.262 section 6.3.3 and table 6-4). </dd> <dt><samp class=”option”>video_format</samp></dt> <dd> Set the video format in the stream (see H.262 section 6.3.6 and table 6-6). </dd> <dt><samp class=”option”>colour_primaries</samp></dt> <dt><samp class=”option”>transfer_characteristics</samp></dt> <dt><samp class=”option”>matrix_coefficients</samp></dt> <dd> Set the colour description in the stream (see H.262 section 6.3.6 and tables 6-7, 6-8 and 6-9). </dd> </dl>

 <h3 class=”section”>2.25 mpeg4_unpack_bframes# TOC</h3>

Unpack DivX-style packed B-frames. DivX-style packed B-frames are not valid MPEG-4 and were only a workaround for the broken Video for Windows subsystem. They use more space, can cause minor AV sync issues, require more CPU power to decode (unless the player has some decoded picture queue to compensate the 2,0,2,0 frame per packet style) and cause trouble if copied into a standard container like mp4 or mpeg-ps/ts, because MPEG-4 decoders may not be able to decode them, since they are not valid MPEG-4. For example to fix an AVI file containing an MPEG-4 stream with DivX-style packed B-frames using <code class=”command”>ffmpeg</code>, you can use the command: <pre class=”example-preformatted”>ffmpeg -i INPUT.avi -codec copy -bsf:v mpeg4_unpack_bframes OUTPUT.avi </pre>

 <h3 class=”section”>2.26 noise# TOC</h3>

Damages the contents of packets or simply drops them without damaging the container. Can be used for fuzzing or testing error resilience/concealment. Parameters: <dl class=”table”> <dt><samp class=”option”>amount</samp></dt> <dd> Accepts an expression whose evaluation per-packet determines how often bytes in that packet will be modified. A value below 0 will result in a variable frequency. Default is 0 which results in no modification. However, if neither amount nor drop is specified, amount will be set to <var class=”var”>-1</var>. See below for accepted variables. </dd> <dt><samp

class=”option”>drop</samp></dt> <dd> Accepts an expression evaluated per-packet whose value determines whether that packet is dropped. Evaluation to a positive value results in the packet being dropped. Evaluation to a negative value results in a variable chance of it being dropped, roughly inverse in proportion to the magnitude of the value. Default is 0 which results in no drops. See below for accepted variables. </dd> <dt><samp class=”option”>dropamount</samp></dt> <dd> Accepts a non-negative integer, which assigns a variable chance of it being dropped, roughly inverse in proportion to the value. Default is 0 which results in no drops. This option is kept for backwards compatibility and is equivalent to setting drop to a negative value with the same magnitude i.e. <code class=”code”>dropamount=4</code> is the same as <code class=”code”>drop=-4</code>. Ignored if drop is also specified. </dd> </dl>

Both <code class=”code”>amount</code> and <code class=”code”>drop</code> accept expressions containing the following variables: <dl class=”table”> <dt>‘<samp class=”samp”>n</samp>’</dt> <dd> The index of the packet, starting from zero. </dd> <dt>‘<samp class=”samp”>tb</samp>’</dt> <dd> The timebase for packet timestamps. </dd> <dt>‘<samp class=”samp”>pts</samp>’</dt> <dd> Packet presentation timestamp. </dd> <dt>‘<samp class=”samp”>dts</samp>’</dt> <dd> Packet decoding timestamp. </dd> <dt>‘<samp class=”samp”>nopts</samp>’</dt> <dd> Constant representing AV_NOPTS_VALUE. </dd> <dt>‘<samp class=”samp”>startpts</samp>’</dt> <dd> First non-AV_NOPTS_VALUE PTS seen in the stream. </dd> <dt>‘<samp class=”samp”>startdts</samp>’</dt> <dd> First non-AV_NOPTS_VALUE DTS seen in the stream. </dd> <dt>‘<samp class=”samp”>duration</samp>’</dt> <dt>‘<samp class=”samp”>d</samp>’</dt <dd> Packet duration, in timebase units. </dd> <dt>‘<samp class=”samp”>pos</samp>’</dt> <dd> Packet position in input; may be -1 when unknown or not set. </dd> <dt>‘<samp class=”samp”>size</samp>’</dt> <dd> Packet size, in bytes. </dd> <dt>‘<samp class=”samp”>key</samp>’</dt> <dd> Whether packet is marked as a keyframe. </dd> <dt>‘<samp class=”samp”>state</samp>’</dt> <dd> A pseudo random integer, primarily derived from the content of packet payload. </dd> </dl>

 <h4 class=”subsection”>2.26.1 Examples# TOC</h4> Apply modification to every byte but don’t drop any packets. <pre class=”example-preformatted”>ffmpeg -i INPUT -c copy -bsf noise=1 output.mkv </pre>

Drop every video packet not marked as a keyframe after timestamp 30s but do not modify any of the remaining packets. <pre class="example-preformatted">ffmpeg -i INPUT -c copy -bsf:v noise=drop='gt(pts*tb\,30)*not(key)' output.mkv </pre>

Drop one second of audio every 10 seconds and add some random noise to the rest. <pre class="example-preformatted">ffmpeg -i INPUT -c copy -bsf:a noise=amount=-1:drop='between(mod(pts*tb\,10)\,9\,10)' output.mkv </pre>

 <h3 class="section">2.27 null# TOC</h3>
This bitstream filter passes the packets through unchanged. <h3 class="section">2.28 pcm_rechunk# TOC</h3>

Repacketize PCM audio to a fixed number of samples per packet or a fixed packet rate per second. This is similar to the <a data-manual="ffmpeg-filters" href="./ffmpeg-filters.html#asetnsamples">asetnsamples audio filter but works on audio packets instead of audio frames. <dl class="table"> <dt><samp class="option">nb_out_samples, n</samp></dt> <dd> Set the number of samples per each output audio packet. The number is intended as the number of samples per each channel. Default value is 1024. </dd> <dt><samp class="option">pad, p</samp></dt> <dd> If set to 1, the filter will pad the last audio packet with silence, so that it will contain the same number of samples (or roughly the same number of samples, see <samp class="option">frame_rate</samp>) as the previous ones. Default value is 1. </dd> <dt><samp class="option">frame_rate, r</samp></dt> <dd> This option makes the filter output a fixed number of packets per second instead of a fixed number of samples per packet. If the audio sample rate is not divisible by the frame rate then the number of samples will not be constant but will vary slightly so that each packet will start as close to the frame boundary as possible. Using this option has precedence over <samp class="option">nb_out_samples</samp>. </dd> </dl>

You can generate the well known 1602-1601-1602-1601-1602 pattern of 48kHz audio for NTSC frame rate using the <samp class="option">frame_rate</samp> option. <pre class="example-preformatted">ffmpeg -f lavfi -i sine=r=48000:d=1 -c pcm_s16le -bsf pcm_rechunk=r=30000/1001 -f framecrc - </pre>

class="pull-right"><a class="anchor hidden-xs" href="#side_005fdata"
aria-hidden="true"># <a class="anchor hidden-xs"href="#toc-
side_005fdata" aria-hidden="true">TOC</h3> Remove
side data from packets and from the stream, or select packets by their
side data. It accepts the following parameters: <dl
class="table"> <dt><samp class="option">remove</samp></dt>
<dd> Set the side data types to remove, joined with ‘<samp
class="samp">+</samp>’, from the packets and from the side data of
the stream. Each type is given by its handle; <code class="command">ffmpeg -
h bsf=side_data</code> lists them. </dd> <dt><samp class="option">select</samp></dt>
<dd> Set the side data types of the packets to keep, joined with
‘<samp class="samp">+</samp>’. A packet is kept if it

carries any of them, and dropped otherwise. The selection looks at the side data before <samp class="option">remove</samp> applies. Dropping a packet breaks the decoding of the packets that depend on it, so this is meant for analysis or for streams where each packet decodes on its own. </dd> </dl>

For example, to drop the display matrix and the replay gain of a stream: <pre class="example-preformatted">ffmpeg -i INPUT -c copy -bsf:v side_data=remove=displaymatrix+replaygain output.mkv </pre>

 <h3 class="section">2.35 smpte436m_to_eia608# TOC</h3>

Convert from a <code class="code">SMPTE_436M_ANC</code> data stream to a <code class="code">EIA_608</code> stream, extracting the closed captions from CTA-708 CDP VANC packets, and ignoring all other data. <h3 class="section">2.36 text2movsub# TOC</h3>

Convert text subtitles to MOV subtitles (as used by the <code class="code">mov_text</code> codec) with metadata headers. See also the mov2textsub filter. <h3 class="section">2.37 trace_headers# TOC</h3>

Log trace output containing all syntax elements in the coded stream headers (everything above the level of individual coded blocks). This can be useful for debugging low-level stream issues. Supports AV1, H.264, H.265, (M)JPEG, MPEG-2 and VP9, but depending on the build only a subset of these may be available. <h3 class="section">2.38 trim# TOC</h3>

Drop packets outside a given range, similar to the trim and atrim filters, but operating on packets instead of decoded frames. The range is described by a <samp class="option">start</samp> and an <samp class="option">end</samp> bound. At least one of them must be set. Each bound is fully described by three independent choices: <ul class="itemize mark-bullet"> The discriminant it is compared against:

the packet’s presentation timestamp, its decoding timestamp, or its index. The two bounds need not use the same one, for instance a <code class=”code”>dts</code> start with a <code class=”code”>pts</code> end. The unit its value is given in: the stream time base, milliseconds, or packets. What it is counted from: zero, or its reference packet when <samp class=”option”>start_rel</samp> / <samp class=”option”>end_rel</samp> is set. For <samp class=”option”>start</samp> the reference packet is the first packet carrying that discriminant. For <samp class=”option”>end</samp> it is the first exported packet.

The <samp class=”option”>start_type</samp> and <samp class=”option”>end_type</samp> options name a combination of the three. The <code class=”code”>dur_ts</code> and <code class=”code”>dur_t_msec</code> end types are the always relative forms of <code class=”code”>pts</code> and <code class=”code”>msec_pt</code>. A zero duration therefore produces an empty stream. Every packet is judged on its own discriminant, and on nothing else. A packet not carrying the discriminant its bound uses cannot be placed, and is dropped. <samp class=”option”>start_rel</samp> makes <samp class=”option”>start</samp> an offset from a reference packet instead of an absolute value. The reference is the first packet carrying the discriminant that bound uses. Its value is added to the offset once, and the bound stays there for the rest of the stream. <samp class=”option”>end_rel</samp> anchors on the first exported packet instead, at the position <samp class=”option”>start</samp> trimmed it to. The two bounds therefore move together. Only a discriminant that cannot come back into the range ends the stream, namely the packet index or the decoding timestamp. End of stream is signaled once one of those passes the <samp class=”option”>end</samp> bound. A presentation timestamp past the end only drops its packet, so that later packets still inside the range are not lost. A bound given in a time unit can fall inside a packet rather than between two. Such a packet is trimmed. Set <samp class=”option”>trim_packets</samp> to false to keep every packet exactly as it came in: exported whole if its own value is inside the range, dropped otherwise. Audio is trimmed in sample space, through skip samples side data. The timestamps and duration are left untouched, and a decoder discards the signaled samples on output. This needs a sample rate and a time base. Audio missing either is rejected rather than trimmed on the timeline. Every other media type is trimmed by shifting the packet timestamps and shortening its duration. Trimming inside an audio packet needs the number of samples it decodes to. Where the codec does not give that number, the packet is handled as though <samp class=”option”>trim_packets</samp> were false. A skip larger than the packet carrying it continues into the packets after it. Dropping such a packet carries the remainder over to the next one. A skip that packet already carries replaces the remainder, as a decoder would, and the larger of it and this filter’s own trim wins. By default a packet outside the range is dropped, whether

or not later packets depend on it. Streams of independent frames, such as ADTS or intra only video, can be cut anywhere. Cutting an inter coded stream inside a group of pictures leaves the first packets in range undecodable. Set <samp class="option">preroll</samp> to export the packets those first packets depend on as well. They are flagged for a decoder to decode and then drop, so the frames it outputs still begin at the <samp class="option">start</samp> bound. Only a decoder acts on that flag. Use <samp class="option">preroll</samp> where the stream is decoded. A muxer writes the extra packets like any other. A remux then covers more than the requested range. <samp class="option">preroll</samp> covers the start of the range only. On a stream with B-frames an <samp class="option">end</samp> bound on the presentation timestamp can drop a packet the last frames in the range need. Those frames then decode incorrectly. It accepts the following parameters: <dl class="table"> <dt><samp class="option">start</samp></dt> <dd> Time or index marking the start of the accepted range. Packets before it are dropped. A packet straddling it is trimmed at its start, or dropped when <samp class="option">trim_packets</samp> is false. </dd> <dt><samp class="option">start_type</samp></dt> <dd> How to interpret <samp class="option">start</samp>: <dl class="table"> <dt>‘<samp class="samp">pts</samp>’</dt> <dd> Presentation timestamp, in stream time base (default). </dd> <dt>‘<samp class="samp">dts</samp>’</dt> <dd> Decoding timestamp, in stream time base. </dd> <dt>‘<samp class="samp">pkt_index</samp>’</dt> <dd> Packet index, counting from zero. </dd> <dt>‘<samp class="samp">msec_pt</samp>’</dt> <dd> Milliseconds, matched against the presentation timestamp. </dd> <dt>‘<samp class="samp">msec_dt</samp>’</dt> <dd> Milliseconds, matched against the decoding timestamp. </dd> </dl>

</dd> <dt><samp class="option">start_rel</samp></dt> <dd> Count <samp class="option">start</samp> from the reference packet rather than from zero. Has no effect on ‘<samp class="samp">pkt_index</samp>’, whose first packet is already zero. Default false. </dd> <dt><samp class="option">end</samp></dt> <dd> Time or index marking the end of the accepted range. Signals end of stream when reached. A packet straddling it is trimmed at its end, or exported untouched when <samp class="option">trim_packets</samp> is false. </dd> <dt><samp class="option">end_type</samp></dt> <dd> How to interpret <samp class="option">end</samp>. Same values as <samp class="option">start_type</samp>, plus: <dl class="table"> <dt>‘<samp class="samp">dur_ts</samp>’</dt> <dd> Duration in stream time base. Same as ‘<samp class="samp">pts</samp>’ with <samp class="option">end_rel</samp> set. </dd> <dt>‘<samp class="samp">dur_t_msec</samp>’</dt> <dd> Duration in milliseconds. Same as ‘<samp class="samp">msec_pt</samp>’

with <samp class=”option”>end_rel</samp> set. </dd> </dl>

</dd> <dt><samp class=”option”>end_rel</samp></dt> <dd> Count <samp class=”option”>end</samp> from the first exported packet rather than from zero. The reference is that packet’s value on the discriminant <samp class=”option”>end_type</samp> names. On a timestamp it is taken at the position the packet is trimmed to. For audio that is the time of its first retained sample. The skip that packet carries can push it past the packet itself. With ‘<samp class=”samp”>pkt_index</samp>’ it exports a fixed number of packets, which can be combined with a timestamp-based <samp class=”option”>start</samp>. Always set for the duration types. Default false. </dd> <dt><samp class=”option”>trim_packets</samp></dt> <dd> Trim packets straddling a boundary. When false, packets are exported exactly as they came in, with no timestamp adjustment and no skip samples side data. A packet is then exported untouched if its value falls inside the range, and dropped otherwise. Default true. </dd> <dt><samp class=”option”>preroll</samp></dt> <dd> Export the packets a decoder needs to decode the first packet in range, rather than dropping them for falling before the <samp class=”option”>start</samp> bound. The filter holds every packet from the last keyframe on. It exports them ahead of the first packet in range, carrying <code class=”code”>AV_PKT_FLAG_DISCARD</code>. Video only. Default false. </dd> <dt><samp class=”option”>preroll_size</samp></dt> <dd> Maximum number of packets held for <samp class=”option”>preroll</samp>. A group of pictures longer than this is dropped whole, with a warning naming the count to raise it past. Default 300, which covers the keyframe intervals encoders commonly default to. </dd> </dl>

For example, to keep only the 10 first packets of an ADTS stream: <pre class=”example-preformatted”>ffmpeg -i INPUT.aac -c copy -bsf:a trim=end=10:end_type=pkt_index OUTPUT.aac </pre>

To keep 5 seconds starting 1.5 seconds into the stream: <pre class=”example-preformatted”>ffmpeg -i INPUT.aac -c copy -bsf:a trim=start=1500:start_type=msec_pt:end=5000:end_type=dur_t_msec OUTPUT.aac </pre>

The same, expressed relative to the first packet so it works regardless of the stream’s starting timestamp: <pre class=”example-preformatted”>ffmpeg -i INPUT.aac -c copy -bsf:a trim=start=1500:start_type=msec_pt:start_rel=1:end=5000:end_type=dur_t_msec OUTPUT.aac </pre>

To start on a keyframeless point of an inter coded video stream, re-encoding it so that the preroll is decoded rather than written out. The filter must run before the decoder, so it is given before the input: <div

class=”example”> <pre class=”example-preformatted”>ffmpeg -bsf:v trim=start=17000:start_type=msec_pt:end=30000:end_type=dur_t_msec:preroll=1 -i INPUT.mp4 OUTPUT.mp4 </pre>

 <h2 class="chapter">1 Description# TOC</h2>

This document describes the codecs (decoders and encoders) provided by the libavcodec library.

 <h2 class="chapter">2 Codec Options# TOC</h2>

libavcodec provides some generic global options, which can be set on all the encoders and decoders. In addition, each codec may support so-called private options, which are specific for a given codec. Sometimes, a global option may only affect a specific kind of codec, and may be nonsensical or ignored by another, so you need to be aware of the meaning of the specified options. Also some options are meant only for decoding or encoding. Options may be set by specifying -<var class="var">option</var> <var class="var">value</var> in the FFmpeg tools, or by setting the value explicitly in the <code class="code">AVCodecContext</code> options or using the <samp class="file">libavutil/opt.h</samp> API for programmatic use. The list of supported options follow: <dl class="table"> <dt><samp class="option">b <var class="var">integer</var> (encoding,audio,video)</samp></dt> <dd> Set bitrate in bits/s. Default value is 200K. </dd> <dt><samp class="option">ab <var class="var">integer</var> (encoding,audio)</samp><
<dd> Set audio bitrate (in bits/s). Default value is 128K. </dd> <dt><samp class="option">bt <var class="var">integer</var> (encoding,video)</samp></dt> <dd> Set video bitrate tolerance (in bits/s). In 1-pass mode, bitrate tolerance specifies how far ratecontrol is willing to deviate from the target average bitrate value. This is not related to min/max bitrate. Lowering tolerance too much has an adverse effect on quality. </dd> <dt><samp class="option">flags <var class="var">flags</var> (decoding/encoding,audio,video,subtitles)</samp></dt> <dd> Set generic flags. Possible values: <dl class="table"> <dt>‘<samp class="samp">mv4</samp>’</dt> <dd> Use four motion vector by macroblock (mpeg4). </dd> <dt>‘<samp class="samp">qpel</samp>’</dt> <dd> Use 1/4 pel motion compensation. </dd> <dt>‘<samp class="samp">loop</samp>’</dt> <dd> Use loop filter. </dd> <dt>‘<samp class="samp">qscale</samp>’</dt> <dd> Use fixed qscale. </dd> <dt>‘<samp class="samp">pass1</samp>’</dt> <dd> Use internal 2pass ratecontrol in first pass mode. </dd> <dt>‘<samp class="samp">pass2</samp>’</dt> <dd> Use internal 2pass ratecontrol in second pass mode. </dd> <dt>‘<samp class="samp">gray</samp>’</dt> <dd> Only decode/encode grayscale. </dd> <dt>‘<samp class="samp">psnr</samp>’</dt> <dd> Set error[?] variables during encoding. </dd> <dt>‘<samp class="samp">truncated</samp>’</dt> <dd> Input bitstream might be randomly truncated. </dd> <dt>‘<samp class="samp">drop_changed</samp>’</dt> <dd> Don’t output frames whose parameters differ from first decoded frame in stream. Error

AVERROR_INPUT_CHANGED is returned when a frame is dropped.
</dd> <dt>‘<samp class="samp">ildct</samp>’</dt>
<dd> Use interlaced DCT. </dd> <dt>‘<samp class="samp">low_delay</samp>’<
<dd> Force low delay. </dd> <dt>‘<samp class="samp">global_header</samp>’<
<dd> Place global headers in extradata instead of every keyframe.
</dd> <dt>‘<samp class="samp">bitexact</samp>’</dt>
<dd> Only write platform-, build- and time-independent data. (except (I)DCT). This ensures that file and data checksums are reproducible and match between platforms. Its primary use is for regression testing.
</dd> <dt>‘<samp class="samp">aic</samp>’</dt>
<dd> Apply H263 advanced intra coding / mpeg4 ac prediction.
</dd> <dt>‘<samp class="samp">ilme</samp>’</dt>
<dd> Apply interlaced motion estimation. </dd> <dt>‘<samp class="samp">cgop</samp>’</dt> <dd> Use closed gop.
</dd> <dt>‘<samp class="samp">output_corrupt</samp>’</dt>
<dd> Output even potentially corrupted frames. </dd> </dl>

</dd>

<dt><samp class="option">time_base <var class="var">rational number</var></samp></dt>

<dd> Set codec time base.

It is the fundamental unit of time (in seconds) in terms of which

frame timestamps are represented. For fixed-fps content, timebase

should be <code class="code">1 / frame_rate</code> and timestamp increments should be

identically 1.

</dd>

<dt><samp class="option">g <var class="var">integer</var> (encoding,video)</samp></dt>

<dd> Set the group of picture (GOP) size. Default value is 12.

</dd>

<dt><samp class="option">ar <var class="var">integer</var> (decoding/encoding,audio)</samp></dt>

<dd> Set audio sampling rate (in Hz).

</dd>

<dt><samp class="option">ac <var class="var">integer</var> (decoding/encoding,audio)</samp></dt>

<dd> Set number of audio channels.

</dd>

<dt><samp class="option">cutoff <var class="var">integer</var> (encoding,audio)</samp></dt>

<dd> Set cutoff bandwidth. (Supported only by selected encoders, see

their respective documentation sections.)

</dd>

<dt><samp class="option">frame_size <var class="var">integer</var> (encoding,audio)</samp></dt>

<dd> Set audio frame size.

Each submitted frame except the last must contain exactly frame_size

samples per channel. May be 0 when the codec has

CODEC_CAP_VARIABLE_FRAME_SIZE set, in that case the frame size is not

restricted. It is set by some decoders to indicate constant frame

size.

</dd>

<dt><samp class="option">frame_number <var class="var">integer</var></samp></dt>

<dd> Set the frame number.

</dd>

<dt><samp class="option">delay <var class="var">integer</var></samp></dt>

<dt><samp class="option">qcomp <var class="var">float</var> (encoding,video)</samp></dt>

<dd> Set video quantizer scale compression (VBR). It is used as a constant

in the ratecontrol equation. Recommended range for default rc_eq:

0.0-1.0.

</dd>

<dt><samp class="option">qblur <var class="var">float</var> (encoding,video)</samp></dt>

<dd> Set video quantizer scale blur (VBR).

</dd>

<dt><samp class="option">qmin <var class="var">integer</var> (encoding,video)</samp></dt>

<dd> Set min video quantizer scale (VBR). Must be included between -1 and

69, default value is 2.

</dd>

<dt><samp class="option">qmax <var class="var">integer</var> (encoding,video)</samp></dt>

<dd> Set max video quantizer scale (VBR). Must be included between -1 and

1024, default value is 31.

</dd>

<dt><samp class="option">qdiff <var class="var">integer</var> (encoding,video)</samp></dt>

<dd> Set max difference between the quantizer scale (VBR).

</dd>

<dt><samp class="option">bf <var class="var">integer</var> (encoding,video)</samp></dt>

<dd> Set max number of B frames between non-B-frames.

Must be an integer between -1 and 16. 0 means that B-frames are

disabled. If a value of -1 is used, it will choose an automatic value

depending on the encoder.

Default value is 0.

</dd>

<dt><samp class="option">b_qfactor <var class="var">float</var> (encoding,video)</samp></dt>

<dd> Set qp factor between P and B frames.

</dd>

<dt><samp class="option">codec_tag <var class="var">integer</var></samp></dt>

<dt><samp class="option">bug <var class="var">flags</var> (decoding,video)</samp></dt>

 <h2 class="chapter">3 Decoders# TOC</h2>

Decoders are configured elements in FFmpeg which allow the decoding of multimedia streams. When you configure your FFmpeg build, all the supported native decoders are enabled by default. Decoders requiring an external library must be enabled manually via the corresponding <code class="code">--enable-lib</code> option. You can list all available decoders using the configure option <code class="code">--list-decoders</code>. You can disable all the decoders with the configure option <code class="code">--disable-decoders</code> and selectively enable / disable single decoders with the options <code class="code">--enable-decoder=<var class="var">DECODER</var></code> / <code class="code">--disable-decoder=<var class="var">DECODER</var></code>. The option <code class="code">-decoders</code> of the ff* tools will display the list of enabled decoders.

 <h2 class="chapter">4 Video Decoders# TOC</h2>

A description of some of the currently available video decoders follows. <h3 class="section">4.1 av1# TOC</h3>

AOMedia Video 1 (AV1) decoder. <h4 class="subsection">4.1.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">operating_point</samp></dt> <dd> Select an operating point of a scalable AV1 bitstream (0 - 31). Default is 0. </dd> </dl>

 <h3 class="section">4.2 hevc# TOC</h3> HEVC (AKA ITU-T H.265 or ISO/IEC 23008-2) decoder. The decoder supports MV-HEVC multiview streams with at most two views. Views to be output are selected by supplying a list of view IDs to the decoder (the <samp class="option">view_ids</samp> option). This op-

tion may be set either statically before decoder init, or from the <code class=”code”>get_format()</code> callback - useful for the case when the view count or IDs change dynamically during decoding. Only the base layer is decoded by default. Note that if you are using the <code class=”code”>ffmpeg</code> CLI tool, you should be using view specifiers as documented in its manual, rather than the options documented here. <h4 class=”subsection”>4.2.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>view_ids (MV-HEVC)</samp></dt> <dd> Specify a list of view IDs that should be output. This option can also be set to a single ’-1’, which will cause all views defined in the VPS to be decoded and output. </dd> <dt><samp class=”option”>view_ids_available (MV-HEVC)</samp></dt> <dd> This option may be read by the caller to retrieve an array of view IDs available in the active VPS. The array is empty for single-layer video. The value of this option is guaranteed to be accurate when read from the <code class=”code”>get_format()</code> callback. It may also be set at other times (e.g. after opening the decoder), but the value is informational only and may be incorrect (e.g. when the stream contains multiple distinct VPS NALUs). </dd> <dt><samp class=”option”>view_pos_available (MV-HEVC)</samp></dt> <dd> This option may be read by the caller to retrieve an array of view positions (left, right, or unspecified) available in the active VPS, as <code class=”code”>AVStereo3DView</code> values. When the array is available, its elements apply to the corresponding elements of <samp class=”option”>view_ids_available</samp>, i.e. <code class=”code”>view_pos_available[i]</code> contains the position of view with ID <code class=”code”>view_ids_available[i]</code>. Same validity restrictions as for <samp class=”option”>view_ids_available</samp> apply to this option. </dd> </dl>

 <h3 class=”section”>4.3 rawvideo# TOC</h3>

Raw video decoder. This decoder decodes rawvideo streams. <h4 class=”subsection”>4.3.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>top <var class=”var”>top_field_first</var></samp></dt
<dd> Specify the assumed field type of the input video. <dl class=”table”> <dt><samp class=”option”>-1</samp></dt> <dd> the video is assumed to be progressive (default) </dd> <dt><samp

class=”option”>0</samp></dt> <dd> bottom-field-first is assumed </dd> <dt><samp class=”option”>1</samp></dt> <dd> top-field-first is assumed </dd> </dl>

</dd> </dl>

 <h3 class=”section”>4.4 libastcenc# TOC</h3>

ARM ASTC Encoder wrapper for decoding ASTC textures. This decoder requires the Arm ASTC Encoder (astc-encoder) library version 5.4 or newer, installed as <code class=”code”>astcenc/astcenc.h</code> next to a library that <code class=”code”>-lastcenc</code> finds. Pass <code class=”code”>--enable-version3</code> together with <code class=”code”>--enable-libastcenc</code> to configure. The <samp class=”file”>.astc</samp> header does not record the intended decoding profile. Individual blocks identify their endpoint encodings, but this does not establish the sRGB versus linear interpretation. The decoder therefore uses the container metadata or <samp class=”option”>dec_profile</samp>: a KTX sRGB texture is decoded as <code class=”code”>ldr-srgb</code>, while a KTX texture in the linear format is sampled with HDR precision (<code class=”code”>hdr-ldr-a</code>, half-float output) because the linear GL internal format says nothing about LDR. A raw <code class=”code”>.astc</code> file carries no profile at all, so it falls back to <code class=”code”>ldr-srgb</code>; use <samp class=”option”>dec_profile</samp> for a raw HDR image: <pre class=”example-preformatted”>ffmpeg -dec_profile hdr-ldr-a -i input.astc output.png </pre>

 <h4 class=”subsection”>4.4.1 Options# TOC</h4> <dl class=”table”> <dt><samp class=”option”>dec_profile <var class=”var”>int</var></samp></dt> <dd> Color profile to decode with, overriding the container metadata. It must match the profile the texture was encoded with: <code class=”code”>astcenc</code> substitutes a fixed magenta error color for blocks whose endpoints do not fit the selected profile. The values are <code class=”code”>ldr</code>, <code class=”code”>ldr-srgb</code>, <code class=”code”>hdr-ldr-a</code> and <code class=”code”>hdr</code>. Without this option the profile published by the container is used; a raw <samp class=”file”>.astc</samp> stream, which publishes none, falls back to <code class=”code”>ldr-srgb</code>. </dd> </dl>

 <h3 class=”section”>4.5 libdav1d<a class=”anchor hidden-xs” href=”#libdav1d” aria-

hidden=”true”># TOC</h3>

dav1d AV1 decoder. libdav1d allows libavcodec to decode the AOMedia Video 1 (AV1) codec. Requires the presence of the libdav1d headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libdav1d</code>. <h4 class=”subsection”>4.5.1 Options# TOC</h4>

The following options are supported by the libdav1d wrapper. <dl class=”table”> <dt><samp class=”option”>max_frame_delay</samp></dt> <dd> Set max amount of frames the decoder may buffer internally. The default value is 0 (autodetect). </dd> <dt><samp class=”option”>filmgrain</samp></dt> <dd> Apply film grain to the decoded video if present in the bitstream. Defaults to the internal default of the library. This option is deprecated and will be removed in the future. See the global option <code class=”code”>export_side_data</code> to export Film Grain parameters instead of applying it. </dd> <dt><samp class=”option”>oppoint</samp></dt> <dd> Select an operating point of a scalable AV1 bitstream (0 - 31). Defaults to the internal default of the library. </dd> <dt><samp class=”option”>alllayers</samp></dt> <dd> Output all spatial layers of a scalable AV1 bitstream. The default value is false. </dd> </dl>

 <h3 class=”section”>4.6 libdavs2# TOC</h3>

AVS2-P2/IEEE1857.4 video decoder wrapper. This decoder allows libavcodec to decode AVS2 streams with davs2 library.

 <h3 class=”section”>4.7 libuavs3d# TOC</h3>

AVS3-P2/IEEE1857.10 video decoder. libuavs3d allows libavcodec to decode AVS3 streams. Requires the presence of the libuavs3d headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libuavs3d</code>. <h4 class=”subsection”>4.7.1 Options# TOC</h4>

The following option is supported by the libuavs3d wrapper. <dl class="table"> <dt><samp class="option">frame_threads</samp></dt> <dd> Set amount of frame threads to use during decoding. The default value is 0 (autodetect). </dd> </dl>

 <h3 class="section">4.8 libxevd# TOC</h3>

eXtra-fast Essential Video Decoder (XEVD) MPEG-5 EVC decoder wrapper. This decoder requires the presence of the libxevd headers and library during configuration. You need to explicitly configure the build with <samp class="option">--enable-libxevd</samp>. The xevd project website is at https://github.com/mpeg5/xevd. <h4 class="subsection">4.8.1 Options# TOC</h4>

The following options are supported by the libxevd wrapper. The xevd-equivalent options or values are listed in parentheses for easy migration. To get a more accurate and extensive documentation of the libxevd options, invoke the command <code class="code">xevd_app --help</code> or consult the libxevd documentation. <dl class="table"> <dt><samp class="option">threads (threads)</samp></dt> <dd> Force to use a specific number of threads </dd> </dl>

 <h3 class="section">4.9 QSV Decoders# TOC</h3>

The family of Intel QuickSync Video decoders (VC1, MPEG-2, H.264, HEVC, JPEG/MJPEG, VP8, VP9, AV1, VVC). <h4 class="subsection">4.9.1 Common Options# TOC</h4>

The following options are supported by all qsv decoders. <dl class="table"> <dt><samp class="option"><var class="var">async_depth</var></samp></dt> <dd> Internal parallelization depth, the higher the value the higher the latency. </dd> <dt><samp class="option"><var class="var">gpu_copy</var></samp></dt> <dd> A GPU-accelerated copy between video and system memory <dl class="table"> <dt>‘<samp class="samp">default</samp>’</dt> <dt>‘<samp class="samp">on</samp>’</dt> <dt>‘<samp class="samp">off</samp>’</dt> </dl>

</dd> </dl>

 <h4 class="subsection">4.9.2 HEVC Options# TOC</h4> Extra options for hevc_qsv. <dl class="table"> <dt><samp class="option"><var class="var">load_plugin</var></samp></dt> <dd> A user plugin to load in an internal session <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dt>‘<samp class="samp">hevc_sw</samp>’<

 <h3 class="section">4.10 v210#
TOC</h3>

Uncompressed 4:2:2 10-bit decoder.
<h4 class="subsection">4.10.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">custom_stride</samp></dt>
<dd> Set the line size of the v210 data in bytes. The default value is 0 (autodetect). You can use the special -1 value for a strideless v210 as seen in BOXX files. </dd> </dl>

 <h2 class="chapter">5 Audio Decoders# TOC</h2>

A description of some of the currently available audio decoders follows. <h3 class="section">5.1 ac3#
TOC</h3>

AC-3 audio decoder. This decoder implements part of ATSC A/52:2010 and ETSI TS 102 366, as well as the undocumented RealAudio 3 (a.k.a. dnet).
<h4 class="subsection">5.1.1 AC-3 Decoder Options# TOC</h4>

<dl class="table"> <dt><samp class="option">-drc_scale <var class="var">value</var></samp></dt>
<dd> Dynamic Range Scale Factor. The factor to apply to dynamic range values from the AC-3 stream. This factor is applied exponentially. The default value is 1. There are 3 notable scale factor ranges: <dl

class=”table”> <dt><samp class=”option”>drc_scale == 0</samp></dt> <dd> DRC disabled. Produces full range audio. </dd> <dt><samp class=”option”>0 < drc_scale <= 1</samp></dt> <dd> DRC enabled. Applies a fraction of the stream DRC value. Audio reproduction is between full range and full compression. </dd> <dt><samp class=”option”>drc_scale > 1</samp></dt> <dd> DRC enabled. Applies drc_scale asymmetrically. Loud sounds are fully compressed. Soft sounds are enhanced. </dd> </dl>

</dd> </dl>

 <h3 class=”section”>5.2 dca# TOC</h3>

DCA (DTS Coherent Acoustics) audio decoder, including the DTS-HD extensions. <h4 class=”subsection”>5.2.1 DCA Decoder Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>-downmix <var class=”var”>channel_layout</var></samp
<dd> Request a smaller channel layout from the decoder: ‘<samp class=”samp”>stereo</samp>’, ‘<samp class=”samp”>5.0(side)</samp>’, ‘<samp class=”samp”>5.1(side)</samp>’ or ‘<samp class=”samp”>7.1</samp>’. A DTS:X stream in the standard presentation decodes to 7.1.4 by default. Its four height channels are carried in an extension at the end of each lossless (XLL) frame, and the encoder also folds them into the 7.1 bed, so the decoder removes them from the bed when it outputs them. Requesting ‘<samp class=”samp”>7.1</samp>’ outputs the bed as coded instead, with the heights folded in, and so does every smaller layout. A ‘<samp class=”samp”>7.1</samp>’ request has no effect on other streams. </dd> </dl>

 <h3 class=”section”>5.3 flac# TOC</h3>

FLAC audio decoder. This decoder aims to implement the complete FLAC specification from Xiph. <h4 class=”subsection”>5.3.1 FLAC Decoder options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>-use_buggy_lpc</samp></dt> <dd> The lavc FLAC encoder used to produce buggy streams with high

lpc values (like the default value). This option makes it possible to decode such streams correctly by using lavc’s old buggy lpc logic for decoding. </dd> </dl>

 <h3 class="section">5.4 ffwavesynth# TOC</h3>

Internal wave synthesizer. This decoder generates wave patterns according to predefined sequences. Its use is purely internal and the format of the data it accepts is not publicly documented. <h3 class="section">5.5 libgsm# TOC</h3>

libgsm decoder wrapper. libgsm allows libavcodec to decode the GSM full rate audio codec. Requires the presence of the libgsm headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libgsm</code>. This decoder supports both the ordinary GSM and the Microsoft variant. <h3 class="section">5.6 libilbc# TOC</h3>

libilbc decoder wrapper. libilbc allows libavcodec to decode the Internet Low Bitrate Codec (iLBC) audio codec. Requires the presence of the libilbc headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libilbc</code>. <h4 class="subsection">5.6.1 Options# TOC</h4>

The following option is supported by the libilbc wrapper. <dl class="table"> <dt><samp class="option">enhance</samp></dt> <dd> Enable the enhancement of the decoded audio when set to 1. The default value is 0 (disabled). </dd> </dl>

 <h3 class="section">5.7 libmpeghdec# TOC</h3>

libmpeghdec decoder wrapper. libmpeghdec allows libmpeghdec to decode the MPEG-H 3D audio codec. Requires the presence of the libmpeghdec headers and library during configuration. You need to

explicitly configure the build with <code class=”code”>--enable-libmpeghdec --enable-nonfree</code>. <h3 class=”section”>5.8 libopencore-amrnb# TOC</h3>

libopencore-amrnb decoder wrapper. libopencore-amrnb allows libavcodec to decode the Adaptive Multi-Rate Narrowband audio codec. Using it requires the presence of the libopencore-amrnb headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libopencore-amrnb</code>. An FFmpeg native decoder for AMR-NB exists, so users can decode AMR-NB without this library. <h3 class=”section”>5.9 libopencore-amrwb# TOC</h

libopencore-amrwb decoder wrapper. libopencore-amrwb allows libavcodec to decode the Adaptive Multi-Rate Wideband audio codec. Using it requires the presence of the libopencore-amrwb headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libopencore-amrwb</code>. An FFmpeg native decoder for AMR-WB exists, so users can decode AMR-WB without this library. <h3 class=”section”>5.10 libopus# TOC</h3>

libopus decoder wrapper. libopus allows libavcodec to decode the Opus Interactive Audio Codec. Requires the presence of the libopus headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libopus</code>. An FFmpeg native decoder for Opus exists, so users can decode Opus without this library. <h3 class=”section”>5.11 pcm_dvda# TOC</h3>

PCM DVD-Audio decoder. Decodes the LPCM variant stored in DVD-Audio AOB files. Unlike DVD-Video LPCM it supports sample rates up to 192 kHz and allows splitting the channels into two groups with different quantization.

 <h2 class=”chapter”>6 Subtitles Decoders# TOC</h2>

 <h3 class="section">6.1 libaribb24# TOC</h3>

<dd> Specify comma-separated list of font family names to be used for bitmap or ass type subtitle rendering. Only first font name is used for ass type subtitle. If not specified, use internally defined default font family. </dd> <dt><samp class=”option”>-ass_single_rect <var class=”var”>boolean</var></samp></dt> <dd> ARIB STD-B24 specifies that some captions may be displayed at different positions at a time (multi-rectangle subtitle). Since some players (e.g., old mpv) can’t handle multiple ASS rectangles in a single AVSubtitle, or multiple ASS rectangles of indeterminate duration with the same start timestamp, this option can change the behavior so that all the texts are displayed in a single ASS rectangle. The default is <var class=”var”>false</var>. If your player cannot handle AVSubtitles with multiple ASS rectangles properly, set this option to <var class=”var”>true</var> or define <code class=”env”>ASS_SINGLE_RECT=1</code> to change default behavior at compilation. </dd> <dt><samp class=”option”>-force_outline_text <var class=”var”>boolean</var></samp></dt> <dd> Specify whether always render outline text for all characters regardless of the indication by character style. The default is <var class=”var”>false</var>. </dd> <dt><samp class=”option”>-outline_width <var class=”var”>number</var> (0.0 - 3.0)</samp></dt> <dd> Specify width for outline text, in dots (relative). The default is <var class=”var”>1.5</var>. </dd> <dt><samp class=”option”>-ignore_background <var class=”var”>boolean</var></samp></dt> <dd> Specify whether to ignore background color rendering. The default is <var class=”var”>false</var>. </dd> <dt><samp class=”option”>-ignore_ruby <var class=”var”>boolean</var></samp></dt> <dd> Specify

whether to ignore rendering for ruby-like (furigana) characters. The default is <var class=”var”>false</var>. </dd> <dt><samp class=”option”>-replace_drcs <var class=”var”>boolean</var></samp></dt> <dd> Specify whether to render replaced DRCS characters as Unicode characters. The default is <var class=”var”>true</var>. </dd> <dt><samp class=”option”>-replace_msz_ascii <var class=”var”>boolean</var></samp></dt> <dd> Specify whether to replace MSZ (Middle Size; half width) fullwidth alphanumerics with halfwidth alphanumerics. The default is <var class=”var”>true</var>. </dd> <dt><samp class=”option”>-replace_msz_japanese <var class=”var”>boolean</var></samp></dt> <dd> Specify whether to replace some MSZ (Middle Size; half width) fullwidth japanese special characters with halfwidth ones. The default is <var class=”var”>true</var>. </dd> <dt><samp class=”option”>-replace_msz_glyph <var class=”var”>boolean</var></samp></dt> <dd> Specify whether to replace MSZ (Middle Size; half width) characters with halfwidth glyphs if the fonts supports it. This option works under FreeType or DirectWrite renderer with Adobe-Japan1 compliant fonts. e.g., IBM Plex Sans JP, Morisawa BIZ UDGothic, Morisawa BIZ UDMincho, Yu Gothic, Yu Mincho, and Meiryo. The default is <var class=”var”>true</var>. </dd> <dt><samp class=”option”>-canvas_size <var class=”var”>image_size</var></samp></dt> <dd> Specify the resolution of the canvas to render subtitles to; usually, this should be frame size of input video. This only applies when <code class=”code”>-subtitle_type</code> is set to <var class=”var”>bitmap</var>. The libaribcaption decoder assumes input frame size for bitmap rendering as below: <ol class=”enumerate”> PROFILE_A : 1440 x 1080 with SAR (PAR) 4:3 PROFILE_C : 320 x 180 with SAR (PAR) 1:1

If actual frame size of input video does not match above assumption, the rendered captions may be distorted. To make the captions undistorted, add <code class=”code”>-canvas_size</code> option to specify actual input video size. Note that the <code class=”code”>-canvas_size</code> option is not required for video with different size but same aspect ratio. In such cases, the caption will be stretched or shrunk to actual video size if <code class=”code”>-canvas_size</code> option is not specified. If <code class=”code”>-canvas_size</code> option is specified with different size, the caption will be stretched or shrunk as specified size with calculated SAR. </dd> </dl>

 <h2 class="chapter">7 Encoders# TOC</h2>

Encoders are configured elements in FFmpeg which allow the encoding of multimedia streams. When you configure your FFmpeg build, all the supported native encoders are enabled by default. Encoders requiring an external library must be enabled manually via the corresponding <code class="code">--enable-lib</code> option. You can list all available encoders using the configure option <code class="code">--list-encoders</code>. You can disable all the encoders with the configure option <code class="code">--disable-encoders</code> and selectively enable / disable single encoders with the options <code class="code">--enable-encoder=<var class="var">ENCODER</var></code> / <code class="code">--disable-encoder=<var class="var">ENCODER</var></code>. The option <code class="code">-encoders</code> of the ff* tools will display the list of enabled encoders.

 <h2 class="chapter">8 Audio Encoders# TOC</h2>

A description of some of the currently available audio encoders follows. <h3 class="section">8.1 aac# TOC</h3>

Advanced Audio Coding (AAC) encoder. This encoder is the default AAC encoder, natively implemented into FFmpeg. <h4 class="subsection">8.1.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">b</samp></dt> <dd> Set bit rate in bits/s. Setting this automatically activates constant bit rate (CBR) mode. If this option is unspecified it is set to 128kbps. </dd> <dt><samp class="option">q</samp></dt> <dd> Set quality for variable bit rate (VBR) mode. This option is valid only using the <code class="command">ffmpeg</code> command-line tool. For library interface users, use <samp class="option">global_quality</samp>. With the default ‘<samp class="samp">nmr</samp>’ coder, VBR holds a constant noise-to-mask target and lets the bitrate follow the content. Higher values are finer: <code class="code">1</code> lands near 128 kbps for typical stereo music, and each doubling of the value raises the rate by roughly a third; values above about 6 make no further difference. A quality setting takes precedence over <samp class="option">b</samp> and <samp class="option">aac_rc</samp>. </dd> <dt><samp class="option">cutoff</samp></dt> <dd> Set cutoff frequency. If unspecified will allow the encoder to dynamically adjust the cutoff to improve clarity on low bitrates. </dd> <dt><samp class="option">aac_coder</samp></dt> <dd> Set AAC encoder coding method. Possible values: <dl class="table"> <dt>‘<samp class="samp">twoloop</samp>’</dt> <dd> Two loop searching (TLS) method. This is the default method. This method first sets quantizers depending on band thresholds and then tries to find an optimal combination by adding or subtracting a specific value from all quantizers and adjusting some individual quantizer a little. Will tune itself based on whether <samp class="option">aac_is</samp>, <samp class="option">aac_ms</samp> and <samp class="option">aac_pns</samp> are enabled. </dd> <dt>‘<samp class="samp">anmr</samp>’</dt> <dd> Average noise to mask ratio (ANMR) trellis-based solution. This is an experimental coder which currently produces a lower quality, is more unstable and is slower than the default twoloop coder but has potential. Currently has no support for the <samp class="option">aac_is</samp> or <samp class="option">aac_pns</samp> options. Not currently recommended. </dd> <dt>‘<samp class="samp">fast</samp>’</dt> <dd> Constant quantizer method. Uses a cheaper version of

twoloop algorithm that doesn’t try to do as many clever adjustments. Worse with low bitrates (less than 64kbps), but is better and much faster at higher bitrates. </dd> </dl>

</dd> <dt><samp class="option">aac_rc</samp></dt> <dd> Rate-control mode of the ‘<samp class="samp">nmr</samp>’ coder when a bitrate is set with <samp class="option">b</samp> (other coders ignore it; <samp class="option">q</samp> takes precedence). Possible values: <dl class="table"> <dt>‘<samp class="samp">cbr</samp>’</dt> <dd> Constant bitrate within the decoder’s bit reservoir. This is the default. </dd> <dt>‘<samp class="samp">abr</samp>’</dt> <dd> Average bitrate: a constant-quality target, as in VBR, whose set-point a slow servo moves to meet <samp class="option">b</samp> over the length of the stream. Local quality stays constant, so short files and individual passages can deviate from the requested rate; the average converges over minutes rather than seconds. Below roughly 56 kbps stereo the rate lands above the request; use ‘<samp class="samp">cbr</samp>’ there. </dd> </dl>

</dd> <dt><samp class="option">aac_ms</samp></dt> <dd> Sets mid/side coding mode. The default value of "auto" will automatically use M/S with bands which will benefit from such coding. Can be forced for all bands using the value "enable", which is mainly useful for debugging or disabled using "disable". </dd> <dt><samp class="option">aac_is</samp></dt> <dd> Sets intensity stereo coding tool usage. By default, it’s enabled and will automatically toggle IS for similar pairs of stereo bands if it’s beneficial. Can be disabled for debugging by setting the value to "disable". </dd> <dt><samp class="option">aac_pns</samp></dt> <dd> Uses perceptual noise substitution to replace low entropy high frequency bands with imperceptible white noise during the decoding process. By default, it’s enabled, but can be disabled for debugging purposes by using "disable". </dd> <dt><samp class="option">aac_tns</samp></dt> <dd> Enables the use of a multitap FIR filter which spans through the high frequency bands to hide quantization noise during the encoding process and is reverted by the decoder. As well as decreasing unpleasant artifacts in the high range this also reduces the entropy in the high bands and allows for more bits to be used by the mid-low bands. By default it’s enabled but can be disabled for debugging by setting the option to "disable". </dd> <dt><samp class="option">aac_ltp</samp></dt> <dd> Enables the use of the long term prediction extension which increases coding efficiency in very low bandwidth situations such as encoding of voice or solo piano music by extending constant harmonic peaks in bands throughout frames. This option is implied by profile:a aac_low. Use in conjunction with <samp class="option">-ar</samp> to decrease the samplerate. </dd> <dt><samp class="option">profile</samp></dt> <dd> Sets the en-

coding profile, possible values: <dl class="table"> <dt>‘<samp class="samp">aac_low</samp>’</dt> <dd> The default, AAC "Low-complexity" profile. Is the most compatible and produces decent quality. </dd> <dt>‘<samp class="samp">mpeg2_aac_low</samp>’</dt> <dd> Equivalent to <code class="code">-profile:a aac_low -aac_pns 0</code>. PNS was introduced with the MPEG4 specifications. </dd> <dt>‘<samp class="samp">aac_ltp</samp>’</dt> <dd> Long term prediction profile, is enabled by and will enable the <samp class="option">aac_ltp</samp> option. Introduced in MPEG4. </dd> </dl> If this option is unspecified it is set to ‘<samp class="samp">aac_low</samp>’. </dd> </dl>

 <h3 class="section">8.2 ac3 and ac3_fixed# TOC</h3>

AC-3 audio encoders. These encoders implement part of ATSC A/52:2010 and ETSI TS 102 366. The <var class="var">ac3</var> encoder uses floating-point math, while the <var class="var">ac3_fixed</var> encoder only uses fixed-point integer math. This does not mean that one is always faster, just that one or the other may be better suited to a particular system. The <var class="var">ac3_fixed</var> encoder is not the default codec for any of the output formats, so it must be specified explicitly using the option <code class="code">-acodec ac3_fixed</code> in order to use it. <h4 class="subsection">8.2.1 AC-3 Metadata# TOC</h4>

The AC-3 metadata options are used to set parameters that describe the audio, but in most cases do not affect the audio encoding itself. Some of the options do directly affect or influence the decoding and playback of the resulting bitstream, while others are just for informational purposes. A few of the options will add bits to the output stream that could otherwise be used for audio data, and will thus affect the quality of the output. Those will be indicated accordingly with a note in the option list below. These parameters are described in detail in several publicly-available documents. <ul class="itemize mark-bullet"> A/52:2010 - Digital Audio Compression (AC-3) (E-AC-3) Standard A/54 - Guide to the Use of the ATSC Digital Television Standard <a class="uref" href="http://www.dolby.com/uploadedFiles/zz-_Shared_Assets/English_PDFs/Professional/18 Metadata Guide Dolby Digital Professional Encoding Guidelines

 <h3 class="section">8.10 libopus# TOC</h3>

libopus Opus Interactive Audio Codec encoder wrapper. Requires the presence of the libopus headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libopus</code>. <h4 class="subsection">8.10.1 Option Mapping# TOC</h4>

Most libopus options are modelled after the <code class="command">opusenc</code> utility from opus-tools. The following is an option mapping chart describing options supported by the libopus wrapper, and their <code class="command">opusenc</code>-equivalent in parentheses. <dl class="table"> <dt><samp class="option">b (bitrate)</samp></dt>

<dd> Set the bit rate in bits/s. FFmpeg’s <samp class="option">b</samp> option is expressed in bits/s, while <code class="command">opusenc</code>’s <samp class="option">bitrate</samp> in kilobits/s. </dd> <dt><samp class="option">vbr (vbr, hard-cbr, and cvbr)</samp></dt> <dd> Set VBR mode. The FFmpeg <samp class="option">vbr</samp> option has the following valid arguments, with the <code class="command">opusenc</code> equivalent options in parentheses: <dl class="table"> <dt>‘<samp class="samp">off (hard-cbr)</samp>’</dt> <dd> Use constant bit rate encoding. </dd> <dt>‘<samp class="samp">on (vbr)</samp>’</dt> <dd> Use variable bit rate encoding (the default). </dd> <dt>‘<samp class="samp">constrained (cvbr)</samp>’</dt> <dd> Use constrained variable bit rate encoding. </dd> </dl>

</dd> <dt><samp class="option">compression_level (comp)</samp></dt> <dd> Set encoding algorithm complexity. Valid options are integers in the 0-10 range. 0 gives the fastest encodes but lower quality, while 10 gives the highest quality but slowest encoding. The default is 10. </dd> <dt><samp class="option">frame_duration (framesize)</samp></dt> <dd> Set maximum frame size, or duration of a frame in milliseconds. The argument must be exactly the following: 2.5, 5, 10, 20, 40, 60. Smaller frame sizes achieve lower latency but less quality at a given bitrate. Sizes greater than 20ms are only interesting at fairly low bitrates. The default is 20ms. </dd> <dt><samp class="option">packet_loss (expect-loss)</samp></dt> <dd> Set expected packet loss percentage. The default is 0. </dd> <dt><samp class="option">fec (n/a)</samp></dt> <dd> Enable inband forward error correction. <samp class="option">packet_loss</samp> must be non-zero to take advantage - frequency of FEC ’side-data’ is proportional to expected packet loss. Default is disabled. </dd> <dt><samp class="option">application (N.A.)</samp></dt> <dd> Set intended application type. Valid options are listed below: <dl class="table"> <dt>‘<samp class="samp">voip</samp>’</dt> <dd> Favor improved speech intelligibility. </dd> <dt>‘<samp class="samp">audio</samp>’</dt> <dd> Favor faithfulness to the input (the default). </dd> <dt>‘<samp class="samp">lowdelay</samp>’</dt> <dd> Restrict to only the lowest delay modes by disabling voice-optimized modes. </dd> </dl>

</dd> <dt><samp class="option">cutoff (N.A.)</samp></dt> <dd> Set cutoff bandwidth in Hz. The argument must be exactly one of the following: 4000, 6000, 8000, 12000, or 20000, corresponding to narrowband, mediumband, wideband, super wideband, and fullband respectively. The default is 0 (cutoff disabled). Note that libopus forces a wideband cutoff for bitrates < 15 kbps, unless CELT-only (<samp class="option">application</samp>

set to ‘<samp class="samp">lowdelay</samp>’) mode is used. </dd> <dt><samp class="option">mapping_family (mapping_family)</samp></dt> <dd> Set channel mapping family to be used by the encoder. The default value of -1 uses mapping family 0 for mono and stereo inputs, and mapping family 1 otherwise. The default also disables the surround masking and LFE bandwidth optimizations in libopus, and requires that the input contains 8 channels or fewer. Other values include 0 for mono and stereo, 1 for surround sound with masking and LFE bandwidth optimizations, and 255 for independent streams with an unspecified channel layout. </dd> <dt><samp class="option">dtx (N.A.)</samp></dt> <dd> Allow discontinuous transmission when set to 1. The default value is 0 (disabled). </dd> <dt><samp class="option">apply_phase_inv (N.A.) (requires libopus >= 1.2)</samp></dt> <dd> If set to 0, disables the use of phase inversion for intensity stereo, improving the quality of mono downmixes, but slightly reducing normal stereo quality. The default is 1 (phase inversion enabled). </dd> </dl>

 <h3 class="section">8.11 libshine# TOC</h3>

Shine Fixed-Point MP3 encoder wrapper. Shine is a fixed-point MP3 encoder. It has a far better performance on platforms without an FPU, e.g. armel CPUs, and some phones and tablets. However, as it is more targeted on performance than quality, it is not on par with LAME and other production-grade encoders quality-wise. Also, according to the project’s homepage, this encoder may not be free of bugs as the code was written a long time ago and the project was dead for at least 5 years. This encoder only supports stereo and mono input. This is also CBR-only. The original project (last updated in early 2007) is at http://sourceforge.net/projects/libshine-fxp/. We only support the updated fork by the Savonet/Liquidsoap project at https://github.com/savonet/shine. Requires the presence of the libshine headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libshine</code>. See also libmp3lame. <h4 class="subsection">8.11.1 Options# TOC</h4>

The following options are supported by the libshine wrapper. The <code class="command">shineenc</code>-equivalent of the options are listed in parentheses. <dl class="table"> <dt><samp class="option">b (<em

class=”emph”>-b)</samp></dt> <dd> Set bitrate expressed in bits/s for CBR. <code class=”command”>shineenc</code> <samp class=”option”>-b</samp> option is expressed in kilobits/s. </dd> </dl>

 <h3 class=”section”>8.12 libtwolame# TOC</h3>

TwoLAME MP2 encoder wrapper. Requires the presence of the libtwolame headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libtwolame</code>. <h4 class=”subsection”>8.12.1 Options# TOC</h4>

The following options are supported by the libtwolame wrapper. The <code class=”command”>twolame</code>-equivalent options follow the FFmpeg ones and are in parentheses. <dl class=”table”> <dt><samp class=”option”>b (-b)</samp></dt> <dd> Set bitrate expressed in bits/s for CBR. <code class=”command”>twolame</code> <samp class=”option”>b</samp> option is expressed in kilobits/s. Default value is 128k. </dd> <dt><samp class=”option”>q (-V)</samp></dt> <dd> Set quality for experimental VBR support. Maximum value range is from -50 to 50, useful range is from -10 to 10. The higher the value, the better the quality. This option is valid only using the <code class=”command”>ffmpeg</code> command-line tool. For library interface users, use <samp class=”option”>global_quality</samp>. </dd> <dt><samp class=”option”>mode (--mode)</samp></dt> <dd> Set the mode of the resulting audio. Possible values: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Choose mode automatically based on the input. This is the default. </dd> <dt>‘<samp class=”samp”>stereo</samp>’</dt> <dd> Stereo </dd> <dt>‘<samp class=”samp”>joint_stereo</samp>’</dt> <dd> Joint stereo </dd> <dt>‘<samp class=”samp”>dual_channel</samp>’</dt> <dd> Dual channel </dd> <dt>‘<samp class=”samp”>mono</samp>’</dt> <dd> Mono </dd> </dl>

</dd> <dt><samp class=”option”>psymodel (--psyc-mode)</samp></dt> <dd> Set psychoacoustic model to use in encoding. The argument must be an integer between -1 and 4, inclusive. The higher the value, the better the quality. The default value is 3. </dd> <dt><samp class=”option”>energy_levels (--energy)</samp></dt> <dd> Enable energy levels extensions when set to 1. The default value is 0 (dis-

abled). </dd> <dt><samp class="option">error_protection (--protect)</samp></dt> <dd> Enable CRC error protection when set to 1. The default value is 0 (disabled). </dd> <dt><samp class="option">copyright (--copyright)</samp></dt> <dd> Set MPEG audio copyright flag when set to 1. The default value is 0 (disabled). </dd> <dt><samp class="option">original (--original)</samp></dt> <dd> Set MPEG audio original flag when set to 1. The default value is 0 (disabled). </dd> </dl>

 <h3 class="section">8.13 libvo-amrwbenc# TOC</h3>

VisualOn Adaptive Multi-Rate Wideband encoder. Requires the presence of the libvo-amrwbenc headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libvo-amrwbenc --enable-version3</code>. This is a mono-only encoder. Officially it only supports 16000Hz sample rate, but you can override it by setting <samp class="option">strict</samp> to ‘<samp class="samp">unofficial</samp>’ or lower. <h4 class="subsection">8.13.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">b</samp></dt> <dd> Set bitrate in bits/s. Only the following bitrates are supported, otherwise libavcodec will round to the nearest valid bitrate. <dl class="table"> <dt>‘<samp class="samp">6600</samp>’</dt> <dt>‘<samp class="samp">8850</samp>’</dt> <dt>‘<samp class="samp">12650</samp>’</dt> <dt>‘<samp class="samp">14250</samp>’</dt> <dt>‘<samp class="samp">15850</samp>’</dt> <dt>‘<samp class="samp">18250</samp>’</dt> <dt>‘<samp class="samp">19850</samp>’</dt> <dt>‘<samp class="samp">23050</samp>’</dt> <dt>‘<samp class="samp">23850</samp>’</dt> </dl>

</dd> <dt><samp class="option">dtx</samp></dt> <dd> Allow discontinuous transmission (generate comfort noise) when set to 1. The default value is 0 (disabled). </dd> </dl>

 <h3 class="section">8.14 libvorbis# TOC</h3>

libvorbis encoder wrapper. Requires the presence of the libvorbisenc headers and library during configuration. You need to explicitly configure

the build with <code class=”code”>--enable-libvorbis</code>. <h4 class=”subsection”>8.14.1 Options# TOC</h4>

The following options are supported by the libvorbis wrapper. The <code class=”command”>oggenc</code>-equivalent of the options are listed in parentheses. To get a more accurate and extensive documentation of the libvorbis options, consult the libvorbisenc’s and <code class=”command”>oggenc</code>’s documentations. See http://xiph.org/vorbis/, http://wiki.xiph.org/Vorbis-tools, and oggenc(1). <dl class=”table”> <dt><samp class=”option”>b (-b)</samp></dt> <dd> Set bitrate expressed in bits/s for ABR. <code class=”command”>oggenc</code> <samp class=”option”>-b</samp> is expressed in kilobits/s. </dd> <dt><samp class=”option”>q (-q)</samp></dt> <dd> Set constant quality setting for VBR. The value should be a float number in the range of -1.0 to 10.0. The higher the value, the better the quality. The default value is ‘<samp class=”samp”>3.0</samp>’. This option is valid only using the <code class=”command”>ffmpeg</code> command-line tool. For library interface users, use <samp class=”option”>global_quality</samp>. </dd> <dt><samp class=”option”>cutoff (--advanced-encode-option lowpass_frequency=N)</samp></dt> <dd> Set cutoff bandwidth in Hz, a value of 0 disables cutoff. <code class=”command”>oggenc</code>’s related option is expressed in kHz. The default value is ‘<samp class=”samp”>0</samp>’ (cutoff disabled). </dd> <dt><samp class=”option”>minrate (-m)</samp></dt> <dd> Set minimum bitrate expressed in bits/s. <code class=”command”>oggenc</code> <samp class=”option”>-m</samp> is expressed in kilobits/s. </dd> <dt><samp class=”option”>maxrate (-M)</samp></dt> <dd> Set maximum bitrate expressed in bits/s. <code class=”command”>oggenc</code> <samp class=”option”>-M</samp> is expressed in kilobits/s. This only has effect on ABR mode. </dd> <dt><samp class=”option”>iblock (--advanced-encode-option impulse_noisetune=N)</samp></dt> <dd> Set noise floor bias for impulse blocks. The value is a float number from -15.0 to 0.0. A negative bias instructs the encoder to pay special attention to the crispness of transients in the encoded audio. The tradeoff for better transient response is a higher bitrate. </dd> </dl>

 <h3 class=”section”>8.15 mjpeg# TOC</h3>

Motion JPEG encoder. <h4 class="subsection">8.15.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">huffman</samp></dt> <dd> Set the huffman encoding strategy. Possible values: <dl class="table"> <dt>‘<samp class="samp">default</samp>’</dt> <dd> Use the default huffman tables.  <h3 class="section">9.8 libaom-av1# TOC</h3>

libaom AV1 encoder wrapper. Requires the presence of the libaom headers and library during configuration. You need to explicitly configure the build with <code class="code">--enable-libaom</code>. <h4 class="subsection">9.8.1 Options# TOC</h4>

The wrapper supports the following standard libavcodec options: <dl class="table"> <dt><samp class="option">b</samp></dt> <dd> Set bitrate target in bits/second. By default this will use variable-bitrate mode. If <samp class="option">maxrate</samp> and <samp class="option">minrate</samp> are also set to the same value then it will use constant-bitrate mode, otherwise if <samp class="option">crf</samp> is set as well then it will use constrained-quality mode. </dd> <dt><samp class="option">g keyint_min</samp></dt> <dd> Set key frame placement. The GOP size sets the maximum distance between key frames; if zero the output stream will be intra-only. The minimum distance is ignored unless it is the same as the GOP size, in which case key frames will always appear at a fixed interval. Not set by default, so without this

option the library has completely free choice about where to place key frames. </dd> <dt><samp class="option">qmin qmax</samp></dt> <dd> Set minimum/maximum quantisation values. Valid range is from 0 to 63 (warning: this does not match the quantiser values actually used by AV1 - divide by four to map real quantiser values to this range). Defaults to min/max (no constraint). </dd> <dt><samp class="option">minrate maxrate bufsize rc_init_occupancy</samp></dt> <dd> Set rate control buffering parameters. Not used if not set - defaults to unconstrained variable bitrate. </dd> <dt><samp class="option">threads</samp></dt> <dd> Set the number of threads to use while encoding. This may require the <samp class="option">tiles</samp> or <samp class="option">row-mt</samp> options to also be set to actually use the specified number of threads fully. Defaults to the number of hardware threads supported by the host machine. </dd> <dt><samp class="option">profile</samp></dt> <dd> Set the encoding profile. Defaults to using the profile which matches the bit depth and chroma subsampling of the input. </dd> </dl>

The wrapper also has some specific options: <dl class="table"> <dt><samp class="option">cpu-used</samp></dt> <dd> Set the quality/encoding speed tradeoff. Valid range is from 0 to 8, higher numbers indicating greater speed and lower quality. The default value is 1, which will be slow and high quality. </dd> <dt><samp class="option">auto-alt-ref</samp></dt> <dd> Enable use of alternate reference frames. Defaults to the internal default of the library. </dd> <dt><samp class="option">arnr-max-frames (frames)</samp></dt> <dd> Set altref noise reduction max frame count. Default is -1. </dd> <dt><samp class="option">arnr-strength (strength)</samp></dt> <dd> Set altref noise reduction filter strength. Range is -1 to 6. Default is -1. </dd> <dt><samp class="option">aq-mode (aq-mode)</samp></dt> <dd> Set adaptive quantization mode. Possible values: <dl class="table"> <dt>‘<samp class="samp">none (0)</samp>’</dt> <dd> Disabled. </dd> <dt>‘<samp class="samp">variance (1)</samp>’</dt> <dd> Variance-based. </dd> <dt>‘<samp class="samp">complexity (2)</samp>’</dt> <dd> Complexity-based. </dd> <dt>‘<samp class="samp">cyclic (3)</samp>’</dt> <dd> Cyclic refresh. </dd> </dl>

</dd> <dt><samp class="option">tune (tune)</samp></dt> <dd> Set the distortion metric the encoder is tuned with. Default is <code class="code">psnr</code>. <dl class="table"> <dt>‘<samp class="samp">psnr (0)</samp>’</dt> <dt>‘<samp class="samp">ssim (1)</samp>’</dt> </dl>

</dd>

<dt><samp class="option">lag-in-frames</samp></dt>

<dd> Set the maximum number of frames which the encoder may keep in flight

at any one time for lookahead purposes. Defaults to the internal

default of the library.

</dd>

<dt><samp class="option">error-resilience</samp></dt>

<dd> Enable error resilience features:

<dl class="table">

<dt><samp class="option">default</samp></dt>

<dd> Improve resilience against losses of whole frames.

</dd>

</dl>

Not enabled by default.

</dd>

<dt><samp class="option">crf</samp></dt>

<dd> Set the quality/size tradeoff for constant-quality (no bitrate target)

and constrained-quality (with maximum bitrate target) modes. Valid

range is 0 to 63, higher numbers indicating lower quality and smaller

output size. Only used if set; by default only the bitrate target is

used.

</dd>

<dt><samp class="option">static-thresh</samp></dt>

<dd> Set a change threshold on blocks below which they will be skipped by

the encoder. Defined in arbitrary units as a nonnegative integer,

defaulting to zero (no blocks are skipped).

</dd>

<dt><samp class="option">drop-threshold</samp></dt>

<dd> Set a threshold for dropping frames when close to rate control bounds.
Defined as a percentage of the target buffer - when the rate control
buffer falls below this percentage, frames will be dropped until it
has refilled above the threshold. Defaults to zero (no frames are
dropped).

</dd>

<dt><samp class="option">denoise-noise-level (level)</samp></dt>

<dd> Amount of noise to be removed for grain synthesis. Grain synthesis is disabled if
this option is not set or set to 0.

</dd>

<dt><samp class="option">denoise-block-size (pixels)</samp></dt>

<dd> Block size used for denoising for grain synthesis. If not set, AV1 codec
uses the default value of 32.

</dd>

<dt><samp class="option">undershoot-pct (pct)</samp></dt>

<dd> Set datarate undershoot (min) percentage of the target bitrate. Range is -1 to 100.
Default is -1.

</dd>

<dt><samp class="option">overshoot-pct (pct)</samp></dt>

<dd> Set datarate overshoot (max) percentage of the target bitrate. Range is -1 to 1000.
Default is -1.

</dd>

<dt><samp class="option">minsection-pct (pct)</samp></dt>

<dd> Minimum percentage variation of the GOP bitrate from the target bitrate. If minsection-pct

is not set, the libaomenc wrapper computes it as follows: <code class="code">(minrate * 100 / bitrate)</code>.

Range is -1 to 100. Default is -1 (unset).

</dd>

<dt><samp class="option">maxsection-pct (pct)</samp></dt>

<dd> Maximum percentage variation of the GOP bitrate from the target bitrate. If maxsection-pct

is not set, the libaomenc wrapper computes it as follows: <code class="code">(maxrate * 100 / bitrate)</code>.

Range is -1 to 5000. Default is -1 (unset).

</dd>

<dt><samp class="option">frame-parallel (boolean)</samp></dt>

<dd> Enable frame parallel decodability features. Default is true.

</dd>

<dt><samp class="option">tiles</samp></dt>

<dd> Set the number of tiles to encode the input video with, as columns x rows. Larger numbers allow greater parallelism in both encoding and

decoding, but may decrease coding efficiency. Defaults to the minimum

number of tiles required by the size of the input video (this is 1x1

(that is, a single tile) for sizes up to and including 4K).

</dd>

<dt><samp class="option">tile-columns tile-rows</samp></dt>

<dd> Set the number of tiles as log2 of the number of tile rows and columns.

Provided for compatibility with libvpx/VP9.

</dd>

<dt><samp class="option">row-mt (Requires libaom >= 1.0.0-759-g90a15f4f2)</samp></dt>

<dd> Enable row based multi-threading. Disabled by default.

</dd>

For example the encoding options might be provided with <samp

class=”option”>-vvenc-params</samp>:   <pre class=”example-preformatted”>ffmpeg -i input -c:v libvvenc -b 1M -vvenc-params intraperiod=64:decodingrefreshtype=idr:poc0idr=1:internalbitdepth=8 output.mp4 </pre>

</dd> </dl>

 <h3 class=”section”>9.18 libwebp# TOC</h3>

libwebp WebP Image encoder wrapper libwebp is Google’s official encoder for WebP images. It can encode in either lossy or lossless mode. Lossy images are essentially a wrapper around a VP8 frame. Lossless images are a separate codec developed by Google. <h4 class=”subsection”>9.18.1 Pixel Format# TOC</h4>

Currently, libwebp only supports YUV420 for lossy and RGB for lossless due to limitations of the format and libwebp. Alpha is supported for either mode. Because of API limitations, if RGB is passed in when encoding lossy or YUV is passed in for encoding lossless, the pixel format will automatically be converted using functions from libwebp. This is not ideal and is done only for convenience. <h4 class=”subsection”>9.18.2 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>-lossless <var class=”var”>boolean</var></samp></dt> <dd> Enables/Disables use of lossless mode. Default is 0. </dd> <dt><samp class=”option”>-compression_level <var class=”var”>integer</var></samp></dt> <dd> For lossy, this is a quality/speed tradeoff. Higher values give better quality for a given size at the cost of increased encoding time. For lossless, this is a size/speed tradeoff. Higher values give smaller size at the cost of increased encoding time. More specifically, it controls the number of extra algorithms and compression tools used, and varies the combination of these tools. This maps to the <var class=”var”>method</var> option in libwebp. The valid range is 0 to 6. Default is 4. </dd> <dt><samp class=”option”>-quality <var class=”var”>float</var></samp></dt> <dd> For lossy encoding, this controls image quality. For lossless encoding, this controls the effort and time spent in compression. Range is 0 to 100.  <h3 class=”section”>9.19 libastcenc<span
class=”pull-right”># <a class=”anchor hidden-xs”href=”#toc-libastcenc-1”
aria-hidden=”true”>TOC</h3>

ARM ASTC Encoder wrapper. This encoder requires the Arm ASTC Encoder (astc-encoder) library version 5.4 or newer, which provides high-quality GPU texture compression to the ASTC format, installed as <code class=”code”>astcenc/astcenc.h</code> next to a library that <code class=”code”>-lastcenc</code> finds. Pass <code class=”code”>--enable-version3</code> together with <code class=”code”>--enable-libastcenc</code> to configure. The encoder supports both LDR (8-bit RGBA/RGB) and HDR (float/half RGBA) input. When float or half input is detected with an LDR profile, the profile is automatically promoted to HDR RGB with LDR alpha (<code class=”code”>HDR_RGB_LDR_A</code>); an explicitly selected HDR profile is kept. The raw bitstream can be packaged in the <samp class=”file”>.astc</samp> container (16-byte header + compressed blocks) or in the Khronos Texture 1.0 container (<samp class=”file”>.ktx</samp>). This implementation writes LDR 2D textures only through the <samp class=”file”>.ktx</samp> muxer: HDR ASTC and 3D block footprints are not supported by the muxer and <samp class=”file”>.astc</samp> must be used for them instead. The KTX 1.0 linear ASTC GL enums do not imply LDR either, so a linear <samp class=”file”>.ktx</samp> texture may still hold HDR endpoints; such a texture is decoded with HDR precision by default. The <samp class=”file”>.ktx</samp> muxer records its row order in a <code class=”code”>KTXorientation</code> key. <h4 class=”subsection”>9.19.1 Pixel Format# TOC</h4>

The encoder accepts the following pixel formats: <ul class=”itemize mark-bullet”> <code class=”code”>rgba</code> – 8-bit packed RGBA (LDR). <code class=”code”>rgb24</code> – 8-bit packed RGB (LDR, opaque alpha synthesized). <code

class=”code”>rgbaf16</code> – 16-bit floating-point RGBA (HDR). <code class=”code”>rgbaf32</code> – 32-bit floating-point RGBA (HDR). <code class=”code”>gbrapf32</code> – planar 32-bit floating-point GBR+Alpha (HDR).

swscale cannot convert to the packed floating-point formats (<code class=”code”>rgbaf16</code>, <code class=”code”>rgbaf32</code>); to encode ordinary image formats as HDR, produce a planar floating-point source instead, for example with <code class=”code”>-vf format=gbrapf32</code>. The packed formats are accepted when they are supplied directly, such as from a decoder or a custom filter graph. <h4 class=”subsection”>9.19.2 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>block_size <var class=”var”>string</var></samp></dt> <dd> ASTC block size specified as <var class=”var”>W</var>x<var class=”var”>H</var>[<code class=”code”>x</code><var class=”var”>D</var>]. When the third dimension is omitted it defaults to 1 (2D block). Valid 2D: 4x4, 5x4, 5x5, 6x5, 6x6, 8x5, 8x6, 8x8, 10x5, 10x6, 10x8, 10x10, 12x10, 12x12. Valid 3D: 3x3x3, 4x3x3, 4x4x3, 4x4x4, 5x4x4, 5x5x4, 5x5x5, 6x5x5, 6x6x5, 6x6x6. Default is <code class=”code”>8x8</code>. </dd> <dt><samp class=”option”>quality <var class=”var”>float</var></samp></dt> <dd> Compression quality from 0 (fastest) to 100 (slowest, exhaustive search). Default is <code class=”code”>60</code>. </dd> <dt><samp class=”option”>profile <var class=”var”>int</var></samp></dt> <dd> Color profile. Possible values: <dl class=”table”> <dt>‘<samp class=”samp”>ldr</samp>’</dt> <dd> Linear LDR. </dd> <dt>‘<samp class=”samp”>ldr-srgb</samp>’</dt> <dd> sRGB LDR (default). </dd> <dt>‘<samp class=”samp”>hdr-ldr-a</samp>’</dt> <dd> HDR RGB channels with LDR alpha channel. </dd> <dt>‘<samp class=”samp”>hdr</samp>’</dt> <dd> Full HDR. </dd> </dl>

When float/half input is detected with an LDR profile, the profile is automatically promoted to <code class=”code”>hdr-ldr-a</code>. Conversely, selecting an HDR profile with 8-bit input is rejected. This option overrides <code class=”code”>AVCodecContext.profile</code>. When it is not set, the profile is taken from <code class=”code”>AVCodecContext.profile</code> (<code class=”code”>AV_PROFILE_ASTC_*</code>), where <code class=”code”>AV_PROFILE_UNKNOWN</code> selects <code class=”code”>ldr-srgb</code> as before. </dd> <dt><samp class=”option”>perceptual <var class=”var”>boolean</var></samp></dt> <dd> Use the perceptual (PSNR-weighted) error metric instead of peak-SNR. Default is <code class=”code”>0</code>. </dd> <dt><samp

class=”option”>alpha_weight <var class=”var”>boolean</var></samp></dt>
<dd> Enable per-texel alpha weighting. Default is <code class=”code”>1</code>.
 </dd> </dl>

 <h3 class=”section”>9.20 libx264, libx264rgb# TOC</h3

x264 H.264/MPEG-4 AVC encoder wrapper. This encoder requires the presence of the libx264 headers and library during configuration. You need to explicitly configure the build with <code class=”code”>--enable-libx264</code>. libx264 supports an impressive number of features, including 8x8 and 4x4 adaptive spatial transform, adaptive B-frame placement, CAVLC/CABAC entropy coding, interlacing (MBAFF), lossless mode, psy optimizations for detail retention (adaptive quantization, psy-RD, psy-trellis). Many libx264 encoder options are mapped to FFmpeg global codec options, while unique encoder options are provided through private options. Additionally the <samp class=”option”>x264opts</samp> and <samp class=”option”>x264-params</samp> private options allows one to pass a list of key=value tuples as accepted by the libx264 <code class=”code”>x264_param_parse</code> function. The x264 project website is at http://www.videolan.org/developers/x264.html
 The libx264rgb encoder is the same as libx264, except it accepts packed RGB pixel formats as input instead of YUV. <h4 class=”subsection”>9.20.1 Supported Pixel Formats# TOC</h4>

x264 supports 8- to 10-bit color spaces. The exact bit depth is controlled at x264’s configure time. <h4 class=”subsection”>9.20.2 Options# TOC</h4>

The following options are supported by the libx264 wrapper. The

<code class=”command”>x264</code>-equivalent options or values are listed in parentheses

for easy migration.

To reduce the duplication of documentation, only the private options

and some others requiring special attention are documented here. For

the documentation of the undocumented generic options, see

the Codec Options chapter.

To get a more accurate and extensive documentation of the libx264

options, invoke the command <code class=”command”>x264 --fullhelp</code> or consult

the libx264 documentation.

In the list below, note that the <code class=”command”>x264</code> option name is shown

in parentheses after the libavcodec corresponding name, in case there

is a direct mapping.

<dl class=”table”>

<dt><samp class=”option”>b (bitrate)</samp></dt>

<dd> Set bitrate in bits/s. Note that FFmpeg’s <samp class=”option”>b</samp> option is

expressed in bits/s, while <code class=”command”>x264</code>’s <samp class=”option”>bitrate</samp> is in

kilobits/s.

 <h3 class=”section”>9.23 libxeve# TOC</h3>

eXtra-fast Essential Video Encoder (XEVE) MPEG-5 EVC encoder wrapper. The xeve-equivalent options or values are listed in parentheses for easy migration. This encoder requires the presence of the libxeve headers and library during configuration. You need to explicitly configure the build with <samp class=”option”>--enable-libxeve</samp>.   Many libxeve encoder options are mapped to FFmpeg global codec options, while unique encoder options are provided through private options. Additionally the xeve-params private options allows one to pass a list of key=value tuples as accepted by the libxeve <code class=”code”>parse_xeve_params</code> function. The xeve project website is at https://github.com/mpeg5/xeve. <h4 class=”subsection”>9.23.1 Options# TOC</h4>

The following options are supported by the libxeve wrapper. The xeve-equivalent options or values are listed in parentheses for easy migration.   To reduce the duplication of documentation, only the private options and some others requiring special attention are documented here. For the documentation of the undocumented generic options, see the Codec Options chapter.   To get a more accurate and extensive documentation of the libxeve options, invoke the command <code class=”code”>xeve_app --help</code> or consult the libxeve documentation. <dl class=”table”> <dt><samp class=”option”>b (bitrate)</samp></dt> <dd> Set target

 <h3 class="section">9.25 MediaCodec# TOC</h3>

MediaCodec encoder wrapper enables hardware-accelerated video encoding on Android device. It supports H.264, H.265 (HEVC), VP8, VP9, MPEG-4, and AV1 encoding (whether works or not is device dependent). Android provides two sets of APIs: Java MediaCodec and NDK MediaCodec. The MediaCodec encoder wrapper supports both. Note that the NDK MediaCodec API operates without requiring JVM, but may fail to function outside the JVM environment due to dependencies on system framework services, particularly after Android 15. <dl class="table"> <dt><samp class="option">ndk_codec <var class="var">boolean</var></samp></dt> <dd> Use the NDK-based MediaCodec API instead of the Java API. Enabled by default if <code class="code">av_jni_get_java_vm()</code> return NULL. </dd> <dt><samp class="option">ndk_async <var class="var">boolean</var></samp></dt> <dd> Use NDK MediaCodec in async mode. Async mode has less overhead than poll in a loop in sync mode. The drawback of async mode is AV_CODEC_FLAG_GLOBAL_HEADER

doesn’t work (use extract_extradata bsf when necessary). It doesn’t work and will be disabled automatically on devices below Android 8.0. </dd> <dt><samp class="option">codec_name <var class="var">string</var></samp></dt> <dd> A codec type can have multiple implementations on a single device, this option specify which backend to use (via MediaCodec createCodecByName API). It’s NULL by default, and encoder is created by createEncoderByType. </dd> <dt><samp class="option">bitrate_mode <var class="var">integer</var></samp></dt> <dd> Possible values: <dl class="table"> <dt>‘<samp class="samp">cq</samp>’</dt> <dd> Constant quality mode </dd> <dt>‘<samp class="samp">vbr</samp>’</dt> <dd> Variable bitrate mode </dd> <dt>‘<samp class="samp">cbr</samp>’</dt> <dd> Constant bitrate mode </dd> <dt>‘<samp class="samp">cbr_fd</samp>’</dt> <dd> Constant bitrate mode with frame drops </dd> </dl>

</dd> <dt><samp class="option">pts_as_dts <var class="var">boolean</var></samp></dt> <dd> Use PTS as DTS. This is a workaround since MediaCodec API doesn’t provide decoding timestamp. It is enabled automatically if B frame is 0. </dd> <dt><samp class="option">operating_rate <var class="var">integer</var></samp></dt> <dd> The desired operating rate that the codec will need to operate at, zero for unspecified. This is used for cases like high-speed/slow-motion video capture, where the video encoder format contains the target playback rate (e.g. 30fps), but the component must be able to handle the high operating capture rate (e.g. 240fps). This rate will be used by codec for resource planning and setting the operating points. </dd> <dt><samp class="option">qp_i_min <var class="var">integer</var></samp></dt> <dd> Minimum quantization parameter for I frame. </dd> <dt><samp class="option">qp_p_min <var class="var">integer</var></samp></dt> <dd> Minimum quantization parameter for P frame. </dd> <dt><samp class="option">qp_b_min <var class="var">integer</var></samp></dt> <dd> Minimum quantization parameter for B frame. </dd> <dt><samp class="option">qp_i_max <var class="var">integer</var></samp></dt> <dd> Maximum quantization parameter for I frame. </dd> <dt><samp class="option">qp_p_max <var class="var">integer</var></samp></dt> <dd> Maximum quantization parameter for P frame. </dd> <dt><samp class="option">qp_b_max <var class="var">integer</var></samp></dt> <dd> Maximum quantization parameter for B frame. </dd> </dl>

 <h3 class="section">9.26 MediaFoundation# TOC</h3>

The following wrappers for encoders in the MediaFoundation frame-

work are available: <ul class="itemize mark-bullet"> h264_mf hevc_mf av1_mf

These support both software and hardware encoding. Video encoders can take input in either of nv12 or yuv420p form (some encoders support both, some support only either - in practice, nv12 is the safer choice, especially among HW encoders). Hardware-accelerated encoding requires D3D11, including hardware scaling capabilities through the scale_d3d11 filter. To list all available options for the MediaFoundation encoders, use: <code class="command">ffmpeg -h encoder=<encoder></code> e.g. <code class="command">ffmpeg -h encoder=h264_mf</code> <h4 class="subsection">9.26.1 Options# TOC</h4>

 <h3 class="section">9.29 NVENC encoders# TOC</h3>

The <code class="code">h264_nvenc</code>, <code class="code">hevc_nvenc</code> and <code class="code">av1_nvenc</code> encoders use NVIDIA NVENC hardware to encode H.264, HEVC and AV1 video, respectively. Building them requires the <code class="code">ffnvcodec</code> headers provided by nv-codec-headers. They are autodetected by configure; they can also be enabled explicitly with <samp class="option">--enable-ffnvcodec</samp> and <samp class="option">--enable-nvenc</samp>. Available options and values depend on the SDK version exposed by the headers at build time. Feature checks in <samp class="file">libavcodec/nvenc.h</samp> distinguish SDK versions 12.0, 12.1, 12.2, 13.0 and 13.1. Runtime support also

depends on the GPU and driver. Use <code class=”command”>ffmpeg -h encoder=hevc_nvenc</code>, or substitute <code class=”code”>h264_nvenc</code> or <code class=”code”>av1_nvenc</code>, to list the options, devices and pixel formats available in a particular build. <h4 class=”subsection”>9.29.1 Hardware input and devices# TOC</h4>

These encoders accept system-memory frames and CUDA hardware frames (<code class=”code”>AV_PIX_FMT_CUDA</code>). Builds using SDK 13.1 or newer also accept CUDA array frames (<code class=”code”>AV_PIX_FMT_CUARRAY</code>). Builds with <code class=”code”>d3d11va</code> support accept D3D11 hardware frames (<code class=”code”>AV_PIX_FMT_D3D11</code>). The input pixel format and encoding features must be supported by the selected GPU. For CUDA decoding followed by encoding, use the input options <samp class=”option”>-hwaccel cuda -hwaccel_output_format cuda</samp> to keep decoded frames on the device. A hardware device can also be created with <samp class=”option”>-init_hw_device</samp> and supplied to the encoder, directly or through its hardware frames context. For system-memory input without a supplied hardware device, the encoder option <samp class=”option”>gpu</samp> selects the device. See its entry under Other common options below. <h4 class=”subsection”>9.29.2 Generic options# TOC</h4>

Several generic encoding options are mapped to NVENC settings. The bitrate options <samp class=”option”>b</samp>, <samp class=”option”>maxrate</samp> and <samp class=”option”>bufsize</samp> set the average bitrate, the maximum bitrate and the VBV buffer size; the NVENC default for <samp class=”option”>b</samp> is ‘<samp class=”samp”>2M</samp>’. <samp class=”option”>g</samp> sets the GOP length, with 0 requesting intra-only encoding. <samp class=”option”>bf</samp> sets the number of B-frames between non-B-frames. <samp class=”option”>refs</samp> sets the number of reference frames in each reference list. <samp class=”option”>g</samp> and <samp class=”option”>bf</samp> default to <code class=”code”>-1</code> and <samp class=”option”>refs</samp> defaults to 0; these defaults leave the values of the preset unchanged. The generic <samp class=”option”>qmin</samp> and <samp class=”option”>qmax</samp> options are honoured in VBR mode with a warning; API users should set the encoder options of the same names listed below instead. Only applications calling the libavcodec API can change <code class=”code”>AVCodecContext.bit_rate</code>,

<code class=”code”>AVCodecContext.rc_max_rate</code> and <code class=”code”>AVCodecContext.rc_buffer_size</code> during encoding. The encoder checks these fields before encoding each frame. When dynamic bitrate changes are supported and rate control is not ‘<samp class=”samp”>constqp</samp>’, changed positive values trigger reconfiguration, reset the encoder and force an IDR. A change to the display aspect ratio also triggers reconfiguration. <h4 class=”subsection”>9.29.3 Common options# TOC</h4>

The following option names are shared by all three encoders. Differences in values and build requirements are noted below. Boolean options accept 0 (disabled) and 1 (enabled), unless otherwise stated. <h4 class=”subsubsection”>9.29.3.1 Presets and tuning# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>preset <var class=”var”>integer</var></samp></dt> <dd> Select the encoding preset using a named value from the table (recommended) or its integer. Apple ProRes encoder. FFmpeg contains 2 ProRes encoders, the prores-aw and prores-ks encoder. The used encoder can be chosen with the <code class="code">-vcodec</code> option. <h4 class="subsection">9.31.1 Private Options for prores-ks# TOC</h4>

<dl class="table"> <dt><samp class="option">profile <var class="var">integer</var></samp></dt>
<dd> Select the ProRes profile to encode <dl class="table">
<dt>‘<samp class="samp">proxy</samp>’</dt> <dt>‘<samp class="samp">lt</samp>’</dt> <dt>‘<samp class="samp">standard</samp>’</dt>
<dt>‘<samp class="samp">hq</samp>’</dt> <dt>‘<samp class="samp">4444</samp>’</dt> <dt>‘<samp class="samp">4444xq</samp>’</dt>
</dl>

</dd> <dt><samp class="option">quant_mat <var class="var">integer</var></samp></dt>
<dd> Select quantization matrix. <dl class="table"> <dt>‘<samp class="samp">auto</samp>’</dt> <dt>‘<samp class="samp">default</samp>’</dt>
<dt>‘<samp class="samp">proxy</samp>’</dt> <dt>‘<samp class="samp">lt</samp>’</dt> <dt>‘<samp class="samp">standard</samp>’</dt>
<dt>‘<samp class="samp">hq</samp>’</dt> </dl> If set to <var class="var">auto</var>, the matrix matching the profile will be picked. If not set, the matrix providing the highest quality, <var class="var">default</var>, will be picked. </dd> <dt><samp class="option">bits_per_mb <var class="var">integer</var></samp></dt>
<dd> How many bits to allot for coding one macroblock. Different profiles use between 200 and 2400 bits per macroblock, the maximum is 8000. </dd> <dt><samp class="option">mbs_per_slice <var class="var">integer</var></samp></dt> <dd> Number of macroblocks in each slice (1-8); the default value (8) should be good in almost all situations. </dd> <dt><samp class="option">vendor <var class="var">string</var></samp></dt> <dd> Override the 4-byte vendor ID. A custom vendor ID like <var class="var">apl0</var> would claim the stream was produced by the Apple encoder. </dd> <dt><samp class="option">alpha_bits <var class="var">integer</var></samp></dt>
<dd> Specify number of bits for alpha component. Possible values are <var class="var">0</var>, <var class="var">8</var> and <var

class=”var”>16</var>. Use <var class=”var”>0</var> to disable alpha plane coding. </dd> </dl>

 <h4 class=”subsection”>9.31.2 Speed considerations# TOC</h4>

In the default mode of operation the encoder has to honor frame constraints (i.e. not produce frames with size bigger than requested) while still making output picture as good as possible. A frame containing a lot of small details is harder to compress and the encoder would spend more time searching for appropriate quantizers for each slice. Setting a higher <samp class=”option”>bits_per_mb</samp> limit will improve the speed. For the fastest encoding speed set the <samp class=”option”>qscale</samp> parameter (4 is the recommended value) and do not set a size constraint. <h3 class=”section”>9.32 QSV Encoders# TOC</h3>

The family of Intel QuickSync Video encoders (MPEG-2, H.264, HEVC, JPEG/MJPEG, VP9, AV1) <h4 class=”subsection”>9.32.1 Ratecontrol Method# TOC</h4> The ratecontrol method is selected as follows: <ul class=”itemize mark-bullet”> When <samp class=”option”>global_quality</samp> is specified, a quality-based mode is used. Specifically this means either <ul class=”itemize mark-minus”> <var class=”var”>CQP</var> - constant quantizer scale, when the <samp class=”option”>qscale</samp> codec flag is also set (the <samp class=”option”>-qscale</samp> ffmpeg option).

<var class=”var”>LA_ICQ</var> - intelligent constant quality with lookahead, when the <samp class=”option”>look_ahead</samp> option is also set.

<var class=”var”>ICQ</var> – intelligent constant quality otherwise. For the ICQ modes, global quality range is 1 to 51, with 1 being the best quality.

Otherwise when the desired average bitrate is specified with the <samp class=”option”>b</samp> option, a bitrate-based mode is used. <ul class=”itemize mark-minus”> <var class=”var”>LA</var> - VBR with lookahead, when the <samp class=”option”>look_ahead</samp> option is specified.

<var class=”var”>VCM</var> - video conferencing mode, when the <samp class=”option”>vcm</samp> option is set.

<var class=”var”>CBR</var> - constant bitrate, when <samp class=”option”>maxrate</samp> is specified and equal to the average bitrate.

<var class=”var”>VBR</var> - variable bitrate, when <samp class=”option”>maxrate</samp> is specified, but is higher than the average bitrate.

<var class=”var”>AVBR</var> - average VBR mode, when <samp class=”option”>maxrate</samp> is not specified, both <samp class=”option”>avbr_accuracy</samp> and <samp class=”option”>avbr_convergence</samp> are set to non-zero. This mode is available for H264 and HEVC on Windows.

Otherwise the default ratecontrol method <var class=”var”>CQP</var> is used.

Note that depending on your system, a different mode than the one you specified may be selected by the encoder. Set the verbosity level to <var class=”var”>verbose</var> or higher to see the actual settings used by the QSV runtime. <h4 class=”subsection”>9.32.2 Global Options -> MSDK Options# TOC</h4> Additional libavcodec global options are mapped to MSDK options as follows: <ul class=”itemize mark-bullet”> <samp class=”option”>g/gop_size</samp> -> <samp class=”option”>GopPicSize</samp>

<samp class=”option”>bf/max_b_frames</samp>+1 -> <samp class=”option”>GopRefDist</samp>

<samp class=”option”>rc_init_occupancy/rc_initial_buffer_occupancy</samp> -> <samp class=”option”>InitialDelayInKB</samp>

<samp class=”option”>slices</samp> -> <samp class=”option”>NumSlice</samp>

<samp class=”option”>refs</samp> -> <samp class=”option”>NumRefFrame</samp>

<samp class=”option”>b_strategy/b_frame_strategy</samp> -> <samp class=”option”>BRefType</samp>

<samp class=”option”>cgop/CLOSED_GOP</samp> codec flag -> <samp class=”option”>GopOptFlag</samp>

For the <var class=”var”>CQP</var> mode, the <samp class=”option”>i_qfactor/i_qoffset</samp> and <samp class=”option”>b_qfactor/b_qoffset</samp> set the difference between <var class=”var”>QPP</var> and <var

class=”var”>QPI</var>, and <var class=”var”>QPP</var> and <var class=”var”>QPB</var> respectively.

Setting the <samp class=”option”>coder</samp> option to the value <var class=”var”>vlc</var> will make the H.264 encoder use CAVLC instead of CABAC.

 <h4 class=”subsection”>9.32.3 Common Options# TOC</h4>
Following options are used by all qsv encoders. <dl class=”table”>
<dt><samp class=”option”><var class=”var”>async_depth</var></samp></dt>
<dd> Specifies how many asynchronous operations an application performs before the application explicitly synchronizes the result. </dd> </dl>

</dd> <dt><samp class="option">hevc_vaapi</samp></dt> <dd> <samp class="option">profile</samp> and <samp class="option">level</samp> set the values of general_profile_idc and general_level_idc respectively. <dl class="table"> <dt><samp class="option">aud</samp></dt> <dd> Include access unit delimiters in the stream (not included by default). </dd> <dt><samp class="option">tier</samp></dt> <dd> Set general_tier_flag. This may affect the level chosen for the stream if it is not explicitly specified. </dd> <dt><samp class="option">sei</samp></dt> <dd> Set SEI message types to include. Some combination of the following values: <dl class="table"> <dt>‘<samp class="samp">hdr</samp>’</dt> <dd> Include HDR metadata if the input frames have it (mastering_display_colour_volume and content_light_level messages). </dd> </dl>

</dd> <dt><samp class="option">tiles</samp></dt> <dd> Set the number of tiles to encode the input video with, as columns x rows. Larger numbers allow greater parallelism in both encoding and decoding, but may decrease coding efficiency. </dd> </dl>

</dd> <dt><samp class="option">mjpeg_vaapi</samp></dt> <dd> Only baseline DCT encoding is supported. The encoder always uses the standard quantisation and huffman tables - <samp class="option">global_quality</samp> scales the standard quantisation table (range 1-100). For YUV, 4:2:0, 4:2:2 and 4:4:4 subsampling modes are supported. RGB is also supported, and will create an RGB JPEG. <dl class="table">

<dt><samp class=”option”>jfif</samp></dt> <dd> Include JFIF header in each frame (not included by default). </dd> <dt><samp class=”option”>huffman</samp></dt> <dd> Include standard huffman tables (on by default). Turning this off will save a few hundred bytes in each output frame, but may lose compatibility with some JPEG decoders which don’t fully handle MJPEG. </dd> </dl>

</dd> <dt><samp class=”option”>mpeg2_vaapi</samp></dt> <dd> <samp class=”option”>profile</samp> and <samp class=”option”>level</samp> set the value of profile_and_level_indication. </dd> <dt><samp class=”option”>vp8_vaapi</samp></dt> <dd> B-frames are not supported. <samp class=”option”>global_quality</samp> sets the q_idx used for non-key frames (range 0-127). <dl class=”table”> <dt><samp class=”option”>loop_filter_level</samp></dt> <dt><samp class=”option”>loop_filter_sharpness</samp></dt> <dd> Manually set the loop filter parameters. </dd> </dl>

</dd> <dt><samp class=”option”>vp9_vaapi</samp></dt> <dd> <samp class=”option”>global_quality</samp> sets the q_idx used for P-frames (range 0-255). <dl class=”table”> <dt><samp class=”option”>loop_filter_level</samp></dt> <dt><samp class=”option”>loop_filter_sharpness</sam
<dd> Manually set the loop filter parameters. </dd> </dl>

B-frames are supported, but the output stream is always in encode order rather than display order. If B-frames are enabled, it may be necessary to use the <samp class=”option”>vp9_raw_reorder</samp> bitstream filter to modify the output stream to display frames in the correct order. Only normal frames are produced - the <samp class=”option”>vp9_superframe</samp> bitstream filter may be required to produce a stream usable with all decoders. </dd> </dl>

 <h3 class=”section”>9.35 vbn# TOC</h3>

Vizrt Binary Image encoder. This format is used by the broadcast vendor Vizrt for quick texture streaming. Advanced features of the format such as LZW compression of texture data or generation of mipmaps are not supported. <h4 class=”subsection”>9.35.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>format <var class=”var”>string</var></samp></dt> <dd> Sets the texture compression used by the VBN file. Can be <var class=”var”>dxt1</var>, <var class=”var”>dxt5</var> or <var class=”var”>raw</var>. Default is <var class=”var”>dxt5</var>. </dd> </dl>

 <h3 class="section">9.36 vc2# TOC</h3>

SMPTE VC-2 (previously BBC Dirac Pro). This codec was primarily aimed at professional broadcasting but since it supports yuv420, yuv422 and yuv444 at 8 (limited range or full range), 10 or 12 bits, this makes it suitable for other tasks which require low overhead and low compression (like screen recording). <h4 class="subsection">9.36.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">b</samp></dt> <dd> Sets target video bitrate. Usually that’s around 1:6 of the uncompressed video bitrate (e.g. for 1920x1080 50fps yuv422p10 that’s around 400Mbps). Higher values (close to the uncompressed bitrate) turn on lossless compression mode. </dd> <dt><samp class="option">field_order</samp></dt> <dd> Enables field coding when set (e.g. to tt - top field first) for interlaced inputs. Should increase compression with interlaced content as it splits the fields and encodes each separately. </dd> <dt><samp class="option">wavelet_depth</samp></dt> <dd> Sets the total amount of wavelet transforms to apply, between 1 and 5 (default). Lower values reduce compression and quality. Less capable decoders may not be able to handle values of <samp class="option">wavelet_depth</samp> over 3. </dd> <dt><samp class="option">wavelet_type</samp></dt> <dd> Sets the transform type. Currently only <var class="var">5_3</var> (LeGall) and <var class="var">9_7</var> (Deslauriers-Dubuc) are implemented, with 9_7 being the one with better compression and thus is the default. </dd> <dt><samp class="option">slice_width</samp></dt> <dt><samp class="option">slice_height</samp></dt> <dd> Sets the slice size for each slice. Larger values result in better compression. For compatibility with other more limited decoders use <samp class="option">slice_width</samp> of 32 and <samp class="option">slice_height</samp> of 8. </dd> <dt><samp class="option">tolerance</samp></dt> <dd> Sets the undershoot tolerance of the rate control system in percent. This is to prevent an expensive search from being run. </dd> <dt><samp class="option">qm</samp></dt> <dd> Sets the quantization matrix preset to use by default or when <samp class="option">wavelet_depth</samp> is set to 5 <ul class="itemize mark-minus"> <var class="var">default</var> Uses the default quantization matrix from the specifications, extended with values for the fifth level. This provides a good balance between keeping detail and omitting artifacts.

<var class="var">flat</var> Use a completely zeroed out quantization matrix. This increases PSNR but might reduce perception. Use in bogus benchmarks.

<var class="var">color</var> Reduces detail but attempts to preserve color at extremely low bitrates.

</dd> </dl>

 <h2 class="chapter">10 Subtitles Encoders# TOC</h2>

 <h3 class="section">10.1 dvbsub# TOC</h3>

This codec encodes the bitmap subtitle format that is used in DVB broadcasts and recordings. The bitmaps are typically embedded in a container such as MPEG-TS as a separate stream. <h4 class="subsection">10.1.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">min_bpp <var class="var">integer (2, 4, or 8)</var></samp></dt> <dd> Set a minimum bits-per-pixel value for the subtitle color lookup tables. DVB supports 2, 4, and 8 bits-per-pixel color lookup tables. This option enables forcing a particular bits-per-pixel value regardless of the number of colors. Since not all players support or properly support 2 bits-per-pixel, this value defaults to 4. </dd> </dl>

 <h3 class="section">10.2 dvdsub# TOC</h3>

This codec encodes the bitmap subtitle format that is used in DVDs. Typically they are stored in VOBSUB file pairs (*.idx + *.sub), and they can also be used in Matroska files. <h4 class="subsection">10.2.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">palette</samp></dt> <dd> Specify the global palette used by the bitmaps. The format for this option is a string containing 16 24-bits hexadecimal numbers (without 0x prefix) separated by commas, for example <code class="code">0d00ee, ee450d, 101010, eaeaea, 0ce60b, ec14ed, ebff0b, 0d617a, 7b7b7b, d1d1d1, 7b2a0e, 0d950c, 0f007b, cf0dec, cfa80c, 7c127b</code>. </dd> <dt><samp class="option">even_rows_fix</samp></dt> <dd> When

set to 1, enable a work-around that makes the number of pixel rows even in all subtitles. This fixes a problem with some players that cut off the bottom row if the number is odd. The work-around just adds a fully transparent row if needed. The overhead is low, typically one byte per subtitle on average. By default, this work-around is disabled. </dd> </dl>

 <h3 class="section">10.3 lrc# TOC</h3>

This codec encodes the LRC lyrics format. <h4 class="subsection">10.3.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">precision</samp></dt> <dd> Specify the precision of the fractional part of the timestamp. Time base is determined based on this value. Defaults to 2 for centiseconds. </dd> </dl>

 <h2 class="chapter">1 Description# TOC</h2>

This document describes the input and output devices provided by the libavdevice library.

 <h2 class="chapter">2 Device Options# TOC</h2>

The libavdevice library provides the same interface as libavformat. Namely, an input device is considered like a demuxer, and an output device like a muxer, and the interface and generic device options are the same provided by libavformat (see the ffmpeg-formats manual). In addition each input or output device may support so-called private options, which are specific for that component. Options may be set by specifying -<var class="var">option</var> <var class="var">value</var> in the FFmpeg tools, or by setting the value explicitly in the device <code class="code">AVFormatContext</code> options or using the <samp class="file">libavutil/opt.h</samp> API for programmatic use.

 <h2 class="chapter">3 Input Devices# TOC</h2>

Input devices are configured elements in FFmpeg which enable accessing the data coming from a multimedia device attached to your system. When you configure your FFmpeg build, all the supported input devices are enabled by default. You can list all available ones using the configure option "–list-indevs". You can disable all the input devices using the configure option "–disable-indevs", and selectively enable an input device using the option "–enable-indev=<var class="var">INDEV</var>", or you can disable a particular input device using the option "–disable-indev=<var class="var">INDEV</var>". The option "-devices" of the ff* tools will display the list of supported input devices. A description of the currently available input devices follows. <h3 class="section">3.1 alsa# TOC</h3>

ALSA (Advanced Linux Sound Architecture) input device. To enable this input device during configuration you need libasound installed on your system. This device allows capturing from an ALSA device. The name of the device to capture has to be an ALSA card identifier. An ALSA identifier has the syntax: <pre class="example-preformatted">hw:<var class="var">CARD</var>[,<var class="var">DEV</var>[,<var class="var">SUBDEV</var>]] </pre>

where the <var class="var">DEV</var> and <var class="var">SUBDEV</var> components are optional. The three arguments (in order: <var class="var">CARD</var>,<var class="var">DEV</var>,<var class="var">SUBDEV</var>) specify card number or identifier, device number and subdevice number (-1 means any). To see the list of cards currently recognized by your system check the files <samp class="file">/proc/asound/cards</samp> and <samp class="file">/proc/asound/devices</samp>. For example to capture with <code class="command">ffmpeg</code> from an ALSA device with card id 0, you may run the command: <pre class="example-preformatted">ffmpeg -f alsa -i hw:0 alsaout.wav </pre>

For more information see: http://www.alsa-project.org/alsa-doc/alsa-lib/pcm.html <h4 class="subsection">3.1.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">sample_rate</samp></dt> <dd> Set the sample rate in Hz. Default is 48000. </dd> <dt><samp class="option">ch_layout</samp></dt> <dd> Set the channel layout. When unset, the layout defaults to stereo, or to the minimum channel count supported by the device, and is filled in from the ALSA channel map on a best-effort basis. </dd> </dl>

 <h3 class="section">3.2 android_camera# TOC</h3>

Android camera input device. This input devices uses the Android Camera2 NDK API which is available on devices with API level 24+. The availability of android_camera is autodetected during configuration. This device allows capturing from all cameras on an Android device, which are integrated into the Camera2 NDK API. The available cameras are enumerated internally and can be selected with the <var class="var">camera_index</var> parameter. The input file string is discarded. Generally the back facing camera has index 0 while the front facing camera has index 1. <h4 class="subsection">3.2.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">video_size</samp></dt> <dd> Set the video size given as a string such as 640x480 or hd720. Falls back to the first available configuration reported by Android if re-

quested video size is not available or by default. </dd> <dt><samp class=”option”>framerate</samp></dt> <dd> Set the video framerate. Falls back to the first available configuration reported by Android if requested framerate is not available or by default (-1). </dd> <dt><samp class=”option”>camera_index</samp></dt> <dd> Set the index of the camera to use. Default is 0. </dd> <dt><samp class=”option”>input_queue_size</samp></dt> <dd> Set the maximum number of frames to buffer. Default is 5. </dd> </dl>

 <h3 class=”section”>3.3 avfoundation# TOC</h3>

AVFoundation input device. AVFoundation is the currently recommended framework by Apple for streamgrabbing on OSX >= 10.7 as well as on iOS. The input filename has to be given in the following syntax: <pre class=”example-preformatted”>-i "[[VIDEO]:[AUDIO]]" </pre> The first entry selects the video input while the latter selects the audio input. The stream has to be specified by the device name or the device index as shown by the device list. Alternatively, the video and/or audio input device can be chosen by index using the <samp class=”option”> -video_device_index <INDEX> </samp> and/or <samp class=”option”> -audio_device_index <INDEX> </samp> , overriding any device name or index given in the input filename. All available devices can be enumerated by using <samp class=”option”>-list_devices true</samp>, listing all device names and corresponding indices. There are two device name aliases: <dl class=”table”> <dt><code class=”code”>default</code></dt> <dd> Select the AVFoundation default device of the corresponding type. </dd> <dt><code class=”code”>none</code></dt> <dd> Do not record the corresponding media type. This is equivalent to specifying an empty device name or index. </dd> </dl>

 <h4 class=”subsection”>3.3.1 Options# TOC</h4>

AVFoundation supports the following options: <dl class=”table”> <dt><samp class=”option”>-list_devices <TRUE|FALSE></samp></dt> <dd> If set to true, a list of all available input devices is given showing their index, name, unique ID, and USB serial number (when available). </dd> <dt><samp class=”option”>-video_device_index <INDEX></samp></dt> <dd> Specify the video device by its index. Overrides anything given in the input filename. </dd> <dt><samp class=”option”>-audio_device_index <INDEX></samp></dt> <dd> Specify the audio device by its index. Overrides anything given in the

input filename. </dd> <dt><samp class=”option”>-video_device_id <ID></samp></dt> <dd> Specify the video device by a prefixed identifier, as shown by <samp class=”option”>-list_devices</samp>: <code class=”code”>uid:<UID></code> selects by AVFoundation unique ID, <code class=”code”>serial:<SERIAL></code> by USB serial number. The unique ID of a UVC device may not be stable across reboots. Only UVC devices expose a serial number. Overrides anything given in the input filename. </dd> <dt><samp class=”option”>-audio_device_id <ID></samp></dt> <dd> Specify the audio device by a prefixed identifier. See <samp class=”option”>-video_device_id</samp>; for audio, the serial is only available for class-compliant USB devices. </dd> <dt><samp class=”option”>-pixel_format <FORMAT></samp></dt> <dd> Request the video device to use a specific pixel format. If the specified format is not supported, a list of available formats is given and the first one in this list is used instead. Available pixel formats are: <code class=”code”>monob, rgb555be, rgb555le, rgb565be, rgb565le, rgb24, bgr24, 0rgb, bgr0, 0bgr, rgb0, bgr48be, uyvy422, yuva444p, yuva444p16le, yuv444p, yuv422p16, yuv422p10, yuv444p10, yuv420p, nv12, yuyv422, gray</code> </dd> <dt><samp class=”option”>-framerate</samp></dt> <dd> Set the grabbing frame rate. Default is <code class=”code”>ntsc</code>, corresponding to a frame rate of <code class=”code”>30000/1001</code>. </dd> <dt><samp class=”option”>-video_size</samp></dt> <dd> Set the video frame size. </dd> <dt><samp class=”option”>-capture_cursor</samp></dt> <dd> Capture the mouse pointer. Default is 0. </dd> <dt><samp class=”option”>-capture_mouse_clicks</samp></dt> <dd> Capture the screen mouse clicks. Default is 0. </dd> <dt><samp class=”option”>-capture_raw_data</samp></dt> <dd> Capture the raw device data. Default is 0. Using this option may result in receiving the underlying data delivered to the AVFoundation framework. E.g. for muxed devices that sends raw DV data to the framework (like tape-based camcorders), setting this option to false results in extracted video frames captured in the designated pixel format only. Setting this option to true results in receiving the raw DV stream untouched. </dd> </dl>

 <h4 class=”subsection”>3.3.2 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Print the list of AVFoundation supported devices and exit: <pre class=”example-preformatted”>$ ffmpeg -f avfoundation -list_devices true -i "" </pre>

Record video from video device 0 and audio from audio device 0 into out.avi: <pre class=”example-preformatted”>$

ffmpeg -f avfoundation -i "0:0" out.avi </pre>

Record video from video device 2 and audio from audio device 1 into out.avi: <pre class="example-preformatted">$ ffmpeg -f avfoundation -video_device_index 2 -i ":1" out.avi </pre>

Record video from the system default video device using the pixel format bgr0 and do not record any audio into out.avi: <pre class="example-preformatted">$ ffmpeg -f avfoundation -pixel_format bgr0 -i "default:none" out.avi </pre>

Record raw DV data from a suitable input device and write the output into out.dv: <pre class="example-preformatted">$ ffmpeg -f avfoundation -capture_raw_data true -i "zr100:none" out.dv </pre>

 <h3 class="section">3.4 decklink# TOC</h3>

The decklink input device provides capture capabilities for Blackmagic DeckLink devices. To enable this input device, you need the Blackmagic DeckLink SDK and you need to configure with the appropriate <code class="code">--extra-cflags</code>, <code class="code">--extra-cxxflags</code> and <code class="code">--extra-ldflags</code>. The SDK include directory must be available to both the C and C++ compilers. On Windows, you need to run the IDL files through <code class="command">widl</code>. DeckLink is very picky about the formats it supports. Pixel format of the input can be set with <samp class="option">raw_format</samp>. Framerate and video size must be determined for your device with <code class="command">-list_formats 1</code>. Audio sample rate is always 48 kHz and the number of channels can be 2, 8 or 16. Note that all audio channels are bundled in one single audio track. <h4 class="subsection">3.4.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">list_devices</samp></dt> <dd> If set to <samp class="option">true</samp>, print a list of devices and exit. Defaults to <samp class="option">false</samp>. This option is deprecated, please use the <code class="code">-sources</code> option of ffmpeg to list the available input devices. </dd> <dt><samp class="option">list_formats</samp></dt> <dd> If set to <samp class="option">true</samp>, print a list of supported formats and

exit. Defaults to <samp class="option">false</samp>. </dd> <dt><samp class="option">format_code <FourCC></samp></dt> <dd> This sets the input video format to the format given by the FourCC. To see the supported values of your device(s) use <samp class="option">list_formats</samp>. Note that there is a FourCC <samp class="option">'pal '</samp> that can also be used as <samp class="option">pal</samp> (3 letters). Default behavior is autodetection of the input video format, if the hardware supports it. </dd> <dt><samp class="option">raw_format</samp></dt> <dd> Set the pixel format of the captured video. Available values are: <dl class="table"> <dt>‘<samp class="samp">auto</samp>’</dt> <dd> This is the default which means 8-bit YUV 422 or 8-bit ARGB if format autodetection is used, 8-bit YUV 422 otherwise. </dd> <dt>‘<samp class="samp">uyvy422</samp>’</dt> <dd> 8-bit YUV 422. </dd> <dt>‘<samp class="samp">yuv422p10</samp>’</dt> <dd> 10-bit YUV 422. </dd> <dt>‘<samp class="samp">argb</samp>’</dt> <dd> 8-bit RGB. </dd> <dt>‘<samp class="samp">bgra</samp>’</dt> <dd> 8-bit RGB. </dd> <dt>‘<samp class="samp">rgb10</samp>’</dt> <dd> 10-bit RGB. </dd> </dl>

</dd> <dt><samp class="option">teletext_lines</samp></dt> <dd> If set to nonzero, an additional teletext stream will be captured from the vertical ancillary data. Both SD PAL (576i) and HD (1080i or 1080p) sources are supported. In case of HD sources, OP47 packets are decoded. This option is a bitmask of the SD PAL VBI lines captured, specifically lines 6 to 22, and lines 318 to 335. Line 6 is the LSB in the mask. Selected lines which do not contain teletext information will be ignored. You can use the special <samp class="option">all</samp> constant to select all possible lines, or <samp class="option">standard</samp> to skip lines 6, 318 and 319, which are not compatible with all receivers. For SD sources, ffmpeg needs to be compiled with <code class="code">--enable-libzvbi</code>. For HD sources, on older (pre-4K) DeckLink card models you have to capture in 10 bit mode. </dd> <dt><samp class="option">channels</samp></dt> <dd> Defines number of audio channels to capture. Must be ‘<samp class="samp">2</samp>’, ‘<samp class="samp">8</samp>’ or ‘<samp class="samp">16</samp>’. Defaults to ‘<samp class="samp">2</samp>’. </dd> <dt><samp class="option">duplex_mode</samp></dt> <dd> Sets the decklink device duplex/profile mode. Must be ‘<samp class="samp">unset</samp>’, ‘<samp class="samp">half</samp>’, ‘<samp class="samp">full</samp>’, ‘<samp class="samp">one_sub_device_full</sa ‘<samp class="samp">one_sub_device_half</samp>’, ‘<samp class="samp">two_sub_device_full</samp>’, ‘<samp class="samp">four_sub_device_half</samp>’ Defaults to ‘<samp class="samp">unset</samp>’. Note: DeckLink SDK 11.0 have replaced the duplex property by a profile property. For the DeckLink Duo 2 and DeckLink Quad 2, a

profile is shared between any 2 sub-devices that utilize the same connectors. For the DeckLink 8K Pro, a profile is shared between all 4 sub-devices. So DeckLink 8K Pro support four profiles. Valid profile modes for DeckLink 8K Pro(with DeckLink SDK >= 11.0): ‘<samp class="samp">one_sub_device_full</samp>’, ‘<samp class="samp">one_sub_device_half</samp>’, ‘<samp class="samp">two_sub_device_full</samp>’, ‘<samp class="samp">four_sub_device_half</samp>’ Valid profile modes for DeckLink Quad 2 and DeckLink Duo 2: ‘<samp class="samp">half</samp>’, ‘<samp class="samp">full</samp>’ </dd> <dt><samp class="option">timecode_format</samp><
<dd> Timecode type to include in the frame and video stream metadata. Must be ‘<samp class="samp">none</samp>’, ‘<samp class="samp">rp188vitc</samp>’, ‘<samp class="samp">rp188vitc2</samp>’, ‘<samp class="samp">rp188ltc</samp>’, ‘<samp class="samp">rp188hfr</samp>’, ‘<samp class="samp">rp188any</samp>’, ‘<samp class="samp">vitc</samp>’, ‘<samp class="samp">vitc2</samp>’, or ‘<samp class="samp">serial</samp>’. Defaults to ‘<samp class="samp">none</samp>’ (not included). In order to properly support 50/60 fps timecodes, the ordering of the queried timecode types for ‘<samp class="samp">rp188any</samp>’ is HFR, VITC1, VITC2 and LTC for >30 fps content. Note that this is slightly different to the ordering used by the DeckLink API, which is HFR, VITC1, LTC, VITC2. </dd> <dt><samp class="option">video_input</samp></dt> <dd> Sets the video input source. Must be ‘<samp class="samp">unset</samp>’, ‘<samp class="samp">sdi</samp>’, ‘<samp class="samp">hdmi</samp>’, ‘<samp class="samp">optical_sdi</samp>’, ‘<samp class="samp">component</samp>’, ‘<samp class="samp">composite</samp>’ or ‘<samp class="samp">s_video</samp>’. Defaults to ‘<samp class="samp">unset</samp>’. </dd> <dt><samp class="option">audio_input</samp></dt> <dd> Sets the audio input source. Must be ‘<samp class="samp">unset</samp>’, ‘<samp class="samp">embedded</samp>’, ‘<samp class="samp">aes_ebu</samp>’, ‘<samp class="samp">analog</samp>’, ‘<samp class="samp">analog_xlr</samp>’, ‘<samp class="samp">analog_rca</samp>’ or ‘<samp class="samp">microphone</samp>’. Defaults to ‘<samp class="samp">unset</samp>’. </dd> <dt><samp class="option">video_pts</samp></dt> <dd> Sets the video packet timestamp source. Must be ‘<samp class="samp">video</samp>’, ‘<samp class="samp">audio</samp>’, ‘<samp class="samp">reference</samp>’, ‘<samp class="samp">wallclock</samp>’ or ‘<samp class="samp">abs_wallclock</samp>’. Defaults to ‘<samp class="samp">video</samp>’. </dd> <dt><samp class="option">audio_pts</samp></dt> <dd> Sets the audio packet timestamp source. Must be ‘<samp class="samp">video</samp>’,

‘<samp class=”samp”>audio</samp>’, ‘<samp class=”samp”>reference</samp>’, ‘<samp class=”samp”>wallclock</samp>’ or ‘<samp class=”samp”>abs_wallclock</samp>’. Defaults to ‘<samp class=”samp”>audio</samp>’. </dd> <dt><samp class=”option”>draw_bars</samp></dt> <dd> If set to ‘<samp class=”samp”>true</samp>’, color bars are drawn in the event of a signal loss. Defaults to ‘<samp class=”samp”>true</samp>’. This option is deprecated, please use the <code class=”code”>signal_loss_action</code> option. </dd> <dt><samp class=”option”>signal_loss_action</samp></dt> <dd> Sets the action to take in the event of a signal loss. Accepts one of the following values: <dl class=”table”> <dt><samp class=”option”>1, none</samp></dt> <dd> Do nothing on signal loss. This usually results in black frames. </dd> <dt><samp class=”option”>2, bars</samp></dt> <dd> Draw color bars on signal loss. Only supported for 8-bit input signals. </dd> <dt><samp class=”option”>3, repeat</samp></dt> <dd> Repeat the last video frame on signal loss. </dd> </dl>

Defaults to ‘<samp class=”samp”>bars</samp>’. </dd> <dt><samp class=”option”>queue_size</samp></dt> <dd> Sets maximum input buffer size in bytes. If the buffering reaches this value, incoming frames will be dropped. Defaults to ‘<samp class=”samp”>1073741824</samp>’. </dd> <dt><samp class=”option”>audio_depth</samp></dt> <dd> Sets the audio sample bit depth. Must be ‘<samp class=”samp”>16</samp>’ or ‘<samp class=”samp”>32</samp>’. Defaults to ‘<samp class=”samp”>16</samp>’. </dd> <dt><samp class=”option”>decklink_copyts</samp></
<dd> If set to <samp class=”option”>true</samp>, timestamps are forwarded as they are without removing the initial offset. Defaults to <samp class=”option”>false</samp>. </dd> <dt><samp class=”option”>timestamp_align</samp></dt> <dd> Capture start time alignment in seconds. If set to nonzero, input frames are dropped till the system timestamp aligns with configured value. Alignment difference of up to one frame duration is tolerated. This is useful for maintaining input synchronization across N different hardware devices deployed for ’N-way’ redundancy. The system time of different hardware devices should be synchronized with protocols such as NTP or PTP, before using this option. Note that this method is not foolproof. In some border cases input synchronization may not happen due to thread scheduling jitters in the OS. Either sync could go wrong by 1 frame or in a rarer case <samp class=”option”>timestamp_align</samp> seconds. Defaults to ‘<samp class=”samp”>0</samp>’. </dd> <dt><samp class=”option”>wait_for_tc (bool)</samp></dt> <dd> Drop frames till a frame with timecode is received. Sometimes serial timecode isn’t received with the first input frame. If that happens,

the stored stream timecode will be inaccurate. If this option is set to <samp class="option">true</samp>, input frames are dropped till a frame with timecode is received. Option <var class="var">timecode_format</var> must be specified. Defaults to <samp class="option">false</samp>. </dd> <dt><samp class="option">enable_klv(bool)</samp></dt> <dd> If set to <samp class="option">true</samp>, extracts KLV data from VANC and outputs KLV packets. KLV VANC packets are joined based on MID and PSC fields and aggregated into one KLV packet. Defaults to <samp class="option">false</samp>. </dd> </dl>

Grab and record the input of a FireWire DV/HDV device, using a packet buffer of 100000 packets if the source is HDV. <pre class=”example-preformatted”>ffmpeg -f iec61883 -i auto -dvbuffer 100000 out.mpg </pre>

 <h3 class=”section”>3.9 jack# TOC</h3>

JACK input device. To enable this input device during configuration you need libjack installed on your system. A JACK input device creates one or more JACK writable clients, one for each audio channel, with name <var class=”var”>client_name</var>:input_<var class=”var”>N</var>, where <var class=”var”>client_name</var> is the name provided by the application, and <var class=”var”>N</var> is a number which identifies the channel. Each writable client will send the acquired data to the FFmpeg input device. Once you have created one or more JACK readable clients, you need to connect them to one or more JACK writable clients. To connect or disconnect JACK clients you can use the <code class=”command”>jack_connect</code> and <code class=”command”>jack_disconnect</code> programs, or do it through a graphical interface, for example with <code class=”command”>qjackctl</code>. To list the JACK clients and their properties you can invoke the command <code class=”command”>jack_lsp</code>. Follows an example which shows how to capture a JACK readable client with <code class=”command”>ffmpeg</code>. <pre

class=”example-preformatted”># Create a JACK writable client with name "ffmpeg". $ ffmpeg -f jack -i ffmpeg -y out.wav

Start the sample jack_metro readable client. $ jack_metro -b 120 -d 0.2 -f 4000

List the current JACK clients. $ jack_lsp -c system:capture_1 system:capture_2 system:playback_1 system:playback_2 ffmpeg:input_1 metro:120_bpm

Connect metro to the ffmpeg writable client. $ jack_connect metro:120_bpm ffmpeg:input_1 </pre>

For more information read: http://jackaudio.org/ <h4 class=”subsection”>3.9.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>channels</samp></dt> <dd> Set the number of channels. Default is 2. </dd> </dl>

 <h3 class=”section”>3.10 kmsgrab# TOC</h3>

KMS video input device. Captures the KMS scanout framebuffer associated with a specified CRTC or plane as a DRM object that can be passed to other hardware functions. Requires either DRM master or CAP_SYS_ADMIN to run. If you don’t understand what all of that means, you probably don’t want this. Look at <samp class=”option”>x11grab</samp> instead. <h4 class=”subsection”>3.10.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>device</samp></dt> <dd> DRM device to capture on. Defaults to <samp class=”option”>/dev/dri/card0</samp>. </dd> <dt><samp class=”option”>format</samp></dt> <dd> Pixel format of the framebuffer. This can be autodetected if you are running Linux 5.7 or later, but needs to be provided for earlier versions. Defaults to <samp class=”option”>bgr0</samp>, which is the most common format used by the Linux console and Xorg X server. </dd> <dt><samp class=”option”>format_modifier</samp></dt> <dd> Format modifier to signal on output frames. This is necessary to import correctly into some APIs. It can be autodetected if you are running Linux 5.7 or later, but will need to be provided explicitly when needed in earlier versions. See the libdrm documentation for possible values. </dd> <dt><samp

class=”option”>crtc_id</samp></dt> <dd> KMS CRTC ID to define the capture source. The first active plane on the given CRTC will be used. </dd> <dt><samp class=”option”>plane_id</samp></dt> <dd> KMS plane ID to define the capture source. Defaults to the first active plane found if neither <samp class=”option”>crtc_id</samp> nor <samp class=”option”>plane_id</samp> are specified. </dd> <dt><samp class=”option”>framerate</samp></dt> <dd> Framerate to capture at. This is not synchronised to any page flipping or framebuffer changes - it just defines the interval at which the framebuffer is sampled. Sampling faster than the framebuffer update rate will generate independent frames with the same content. Defaults to <code class=”code”>30</code>. </dd> </dl>

 <h4 class=”subsection”>3.10.2 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Capture from the first active plane, download the result to normal frames and encode. This will only work if the framebuffer is both linear and mappable - if not, the result may be scrambled or fail to download. <pre class=”example-preformatted”>ffmpeg -f kmsgrab -i - -vf 'hwdownload,format=bgr0' output.mp4 </pre>

Capture from CRTC ID 42 at 60fps, map the result to VAAPI, convert to NV12 and encode as H.264. <pre class=”example-preformatted”>ffmpeg -crtc_id 42 -framerate 60 -f kmsgrab -i - -vf 'hwmap=derive_device=vaapi,scale_vaapi=w=1920:h=1080:format=nv12' -c:v h264_vaapi output.mp4 </pre>

To capture only part of a plane the output can be cropped - this can be used to capture a single window, as long as it has a known absolute position and size. For example, to capture and encode the middle quarter of a 1920x1080 plane: <pre class=”example-preformatted”>ffmpeg -f kmsgrab -i - -vf 'hwmap=derive_device=vaapi,crop=960:540:480:270,scale_vaapi=960:540:nv12' -c:v h264_vaapi output.mp4 </pre>

 <h3 class=”section”>3.11 lavfi# TOC</h3>

Libavfilter input virtual device. This input device reads data from the open output pads of a libavfilter filtergraph. For each filtergraph open output, the input device will create a corresponding stream which is mapped to the generated output. The filtergraph is specified through the option <samp class=”option”>graph</samp>. <a

name=”Options-10”> <h4 class=”subsection”>3.11.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>graph</samp></dt> <dd> Specify the filtergraph to use as input. Each video open output must be labelled by a unique string of the form "out<var class=”var”>N</var>", where <var class=”var”>N</var> is a number starting from 0 corresponding to the mapped input stream generated by the device. The first unlabelled output is automatically assigned to the "out0" label, but all the others need to be specified explicitly. The suffix "+subcc" can be appended to the output label to create an extra stream with the closed captions packets attached to that output (experimental; only for EIA-608 / CEA-708 for now). The subcc streams are created after all the normal streams, in the order of the corresponding stream. For example, if there is "out19+subcc", "out7+subcc" and up to "out42", the stream #43 is subcc for stream #7 and stream #44 is subcc for stream #19. If not specified defaults to the filename specified for the input device. </dd> <dt><samp class=”option”>graph_file</samp></dt> <dd> Set the filename of the filtergraph to be read and sent to the other filters. Syntax of the filtergraph is the same as the one specified by the option <var class=”var”>graph</var>. </dd> <dt><samp class=”option”>dumpgraph</samp></dt> <dd> Dump graph to stderr. </dd> </dl>

 <h4 class=”subsection”>3.11.2 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Create a color video stream and play it back with <code class=”command”>ffplay</code>: <pre class=”example-preformatted”>ffplay -f lavfi -graph "color=c=pink [out0]" dummy </pre>

As the previous example, but use filename for specifying the graph description, and omit the "out0" label: <pre class=”example-preformatted”>ffplay -f lavfi color=c=pink </pre>

Create three different video test filtered sources and play them: <pre class=”example-preformatted”>ffplay -f lavfi -graph "testsrc [out0]; testsrc,hflip [out1]; testsrc,negate [out2]" test3 </pre>

Read an audio stream from a file using the amovie source and play it back with <code class=”command”>ffplay</code>: <pre class=”example-preformatted”>ffplay -f lavfi "amovie=test.wav" </pre>

Read an audio stream and a video stream and play it back with <code class="command">ffplay</code>: <pre class="example-preformatted">ffplay -f lavfi "movie=test.avi[out0];amovie=test.wav[out1]" </pre>

Dump decoded frames to images and Closed Captions to an RCWT backup: <pre class="example-preformatted">ffmpeg -f lavfi -i "movie=test.ts[out0+subcc]" -map v frame%08d.png -map s -c copy -f rcwt subcc.bin </pre>

 <h3 class=”section”>3.17 sndio# TOC</h3>

sndio input device. To enable this input device during configuration you need libsndio installed on your system. The filename to provide to the input device is the device node representing the sndio input device, and is usually set to <samp class=”file”>/dev/audio0</samp>. For example to grab from <samp class=”file”>/dev/audio0</samp> using <code class=”command”>ffmpeg</code> use the command: <pre class=”example-preformatted”>ffmpeg -f sndio -i /dev/audio0 /tmp/oss.wav </pre>

 <h4 class=”subsection”>3.17.1 Options# TOC</h4>

<dl class=”table”> <dt><samp class=”option”>sample_rate</samp></dt> <dd> Set the sample rate in Hz. Default is 48000. </dd> <dt><samp class=”option”>channels</samp></dt> <dd> Set the number of channels. Default is 2. </dd> </dl>

 <h3 class=”section”>3.18 video4linux2, v4l2# TOC</h3

Video4Linux2 input video device. "v4l2" can be used as alias for "video4linux2". If FFmpeg is built with v4l-utils support (by using the <code class=”code”>--enable-libv4l2</code>

configure option), it is possible to use it with the <code class="code">-use_libv4l2</code> input device option. The name of the device to grab is a file device node, usually Linux systems tend to automatically create such nodes when the device (e.g. an USB webcam) is plugged into the system, and has a name of the kind <samp class="file">/dev/video<var class="var">N</var></samp>, where <var class="var">N</var> is a number associated to the device. Video4Linux2 devices usually support a limited set of <var class="var">width</var>x<var class="var">height</var> sizes and frame rates. You can check which are supported using <code class="command">-list_formats all</code> for Video4Linux2 devices. Some devices, like TV cards, support one or more standards. It is possible to list all the supported standards using <code class="command">-list_standards all</code>. The time base for the timestamps is 1 microsecond. Depending on the kernel version and configuration, the timestamps may be derived from the real time clock (origin at the Unix Epoch) or the monotonic clock (origin usually at boot time, unaffected by NTP or manual changes to the clock). The <samp class="option">-timestamps abs</samp> or <samp class="option">-ts abs</samp> option can be used to force conversion into the real time clock. Some usage examples of the video4linux2 device with <code class="command">ffmpeg</code> and <code class="command">ffplay</code>: <ul class="itemize mark-bullet"> List supported formats for a video4linux2 device: <pre class="example-preformatted">ffplay -f video4linux2 -list_formats all /dev/video0 </pre>

Grab and show the input of a video4linux2 device: <pre class="example-preformatted">ffplay -f video4linux2 -framerate 30 -video_size hd720 /dev/video0 </pre>

Grab and record the input of a video4linux2 device, leave the frame rate and size as previously set: <pre class="example-preformatted">ffmpeg -f video4linux2 -input_format mjpeg -i /dev/video0 out.mpeg </pre>

For more information about Video4Linux, check http://linuxtv.org/. <h4 class="subsection">3.18.1 Options# TOC</h4>

corresponding to a frame rate of <code class="code">30000/1001</code>.
 </dd> </dl>

 <h3 class="section">3.20 x11grab# TOC</h3>

X11 video input device. To enable this input device during configuration you need libxcb installed on your system. It will be automatically detected during configuration. This device allows one to capture a region of an X11 display. The filename passed as input has the syntax: <pre class="example-preformatted">[<var class="var">hostname</var>]:<var class="var">display_number</var>.<var class="var">screen_number</var>[+<var class="var">x_offset</var>,<var class="var">y_offset</var>] </pre>

<var class="var">hostname</var>:<var class="var">display_number</var>.<var class="var">screen_number</var> specifies the X11 display name of the screen to grab from. <var class="var">hostname</var> can be omitted, and defaults to "localhost". The environment variable <code class="env">DISPLAY</code> contains the default display name.
<var class="var">x_offset</var> and <var class="var">y_offset</var> specify the offsets of the grabbed area with respect to the top-left border of the X11 screen. They default to 0. Check the X11 documentation (e.g. <code class="command">man X</code>) for more detailed information. Use the <code class="command">xdpyinfo</code> program for getting basic information about the properties of your X11 display (e.g. grep for "name" or "dimensions").
For example to grab from <samp class="file">:0.0</samp> using <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -f x11grab -framerate 25 -video_size cif -i :0.0 out.mpg </pre>

Grab at position <code class="code">10,20</code>: <pre class="example-preformatted">ffmpeg -f x11grab -framerate 25 -video_size cif -i :0.0+10,20 out.mpg </pre>

 <h4 class="subsection">3.20.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">select_region</samp></dt>
<dd> Specify whether to select the grabbing area graphically using the pointer. A value of <code class="code">1</code> prompts the user to select the grabbing area graphically by clicking and drag-

ging. A single click with no dragging will select the whole screen. A region with zero width or height will also select the whole screen. This option overwrites the <var class="var">video_size</var>, <var class="var">grab_x</var>, and <var class="var">grab_y</var> options. Default value is <code class="code">0</code>. </dd> <dt><samp class="option">draw_mouse</samp></dt> <dd> Specify whether to draw the mouse pointer. A value of <code class="code">0</code> specifies not to draw the pointer. Default value is <code class="code">1</code>. </dd> <dt><samp class="option">follow_mouse</samp></dt> <dd> Make the grabbed area follow the mouse. The argument can be <code class="code">centered</code> or a number of pixels <var class="var">PIXELS</var>. When it is specified with "centered", the grabbing region follows the mouse pointer and keeps the pointer at the center of region; otherwise, the region follows only when the mouse pointer reaches within <var class="var">PIXELS</var> (greater than zero) to the edge of region. For example: <pre class="example-preformatted">ffmpeg -f x11grab -follow_mouse centered -framerate 25 -video_size cif -i :0.0 out.mpg </pre>

To follow only when the mouse pointer reaches within 100 pixels to edge: <pre class="example-preformatted">ffmpeg -f x11grab -follow_mouse 100 -framerate 25 -video_size cif -i :0.0 out.mpg </pre>

</dd> <dt><samp class="option">framerate</samp></dt> <dd> Set the grabbing frame rate.  <h3 class="section">4.4 decklink# TOC</h3>

The decklink output device provides playback capabilities for Blackmagic DeckLink devices. To enable this output device, you need the Blackmagic DeckLink SDK and you need to configure with the appropriate <code class="code">--extra-cflags</code>, <code class="code">--extra-cxxflags</code> and <code class="code">--extra-ldflags</code>. The SDK include directory must be available to both the C and C++ compilers. On Windows, you need to run the IDL files through <code class="command">widl</code>. DeckLink is very picky about the formats it supports. Pixel format is always uyvy422, framerate, field order and video size must be determined for your device with <code class="command">-list_formats 1</code>. Audio sample rate is always 48 kHz. <h4 class="subsection">4.4.1 Options# TOC</h4>

<dl class="table"> <dt><samp class="option">list_devices</samp></dt> <dd> If set to <samp class="option">true</samp>, print a list of devices and exit. Defaults to <samp class="option">false</samp>. This option is deprecated, please use the <code class="code">-sinks</code> option of ffmpeg to list the available output devices. </dd> <dt><samp class="option">list_formats</samp></dt> <dd> If set to <samp class="option">true</samp>, print a list of supported formats and exit. Defaults to <samp class="option">false</samp>. </dd> <dt><samp class="option">preroll</samp></dt> <dd> Amount of time to preroll video in seconds. Defaults to <samp class="option">0.5</samp>. </dd> <dt><samp class="option">duplex_mode</samp></dt> <dd> Sets the decklink device duplex/profile mode. Must be ‘<samp class="samp">unset</samp>’, ‘<samp class="samp">half</samp>’,

‘<samp class="samp">full</samp>’, ‘<samp class="samp">one_sub_device_full</sa
‘<samp class="samp">one_sub_device_half</samp>’,
‘<samp class="samp">two_sub_device_full</samp>’,
‘<samp class="samp">four_sub_device_half</samp>’ Defaults to ‘<samp class="samp">unset</samp>’.
Note: DeckLink SDK 11.0 have replaced the duplex property by a profile property. For the DeckLink Duo 2 and DeckLink Quad 2, a profile is shared between any 2 sub-devices that utilize the same connectors. For the DeckLink 8K Pro, a profile is shared between all 4 sub-devices. So DeckLink 8K Pro support four profiles. Valid profile modes for DeckLink 8K Pro(with DeckLink SDK >= 11.0): ‘<samp class="samp">one_sub_device_full</samp>’,
‘<samp class="samp">one_sub_device_half</samp>’,
‘<samp class="samp">two_sub_device_full</samp>’,
‘<samp class="samp">four_sub_device_half</samp>’

 <h2 class="chapter">1 Description# TOC</h2>

This document describes filters, sources, and sinks provided by the libavfilter library.

 <h2 class="chapter">2 Filtering Introduction# TOC</h2>

Filtering in FFmpeg is enabled through the libavfilter library. In libavfilter, a filter can have multiple inputs and multiple outputs. To illustrate the sorts of things that are possible, we consider the following filtergraph. <pre class="verbatim"> [main] input --> split ----------> overlay --> output | ^ |[tmp] [flip]| +-----> crop --> vflip -------+ </pre> This filtergraph splits the input stream in two streams, then sends one stream through the crop filter and the vflip filter, before merging it back with the other stream by overlaying it on top. You can use the following command to achieve this: <pre

class=”example-preformatted”>ffmpeg -i INPUT -vf "split [main][tmp]; [tmp] crop=iw:ih/2:0:0, vflip [flip]; [main][flip] overlay=0:H/2" OUTPUT </pre>

The result will be that the top half of the video is mirrored onto the bottom half of the output video. Filters in the same linear chain are separated by commas, and distinct linear chains of filters are separated by semicolons. In our example, <var class=”var”>crop,vflip</var> are in one linear chain, <var class=”var”>split</var> and <var class=”var”>overlay</var> are separately in another. The points where the linear chains join are labelled by names enclosed in square brackets. In the example, the split filter generates two outputs that are associated to the labels <var class=”var”>[main]</var> and <var class=”var”>[tmp]</var>. The stream sent to the second output of <var class=”var”>split</var>, labelled as <var class=”var”>[tmp]</var>, is processed through the <var class=”var”>crop</var> filter, which crops away the lower half part of the video, and then vertically flipped. The <var class=”var”>overlay</var> filter takes in input the first unchanged output of the split filter (which was labelled as <var class=”var”>[main]</var>), and overlay on its lower half the output generated by the <var class=”var”>crop,vflip</var> filterchain. Some filters take in input a list of parameters: they are specified after the filter name and an equal sign, and are separated from each other by a colon. There exist so-called <var class=”var”>source filters</var> that do not have an audio/video input, and <var class=”var”>sink filters</var> that will not have audio/video output.

 <h2 class=”chapter”>3 graph2dot# TOC</h2>

The <samp class=”file”>graph2dot</samp> program included in the FFmpeg <samp class=”file”>tools</samp> directory can be used to parse a filtergraph description and issue a corresponding textual representation in the dot language. Invoke the command: <pre class=”example-preformatted”>graph2dot -h </pre>

to see how to use <samp class=”file”>graph2dot</samp>. You can then pass the dot description to the <samp class=”file”>dot</samp> program (from the graphviz suite of programs) and obtain a graphical representation of the filtergraph. For example the sequence of commands: <pre class=”example-preformatted”>echo <var class=”var”>GRAPH_DESCRIPTION</var> | \ tools/graph2dot -o graph.tmp && \ dot -Tpng graph.tmp -o graph.png && \ display graph.png </pre>

can be used to create and display an image representing the graph described by the <var class=”var”>GRAPH_DESCRIPTION</var> string.

Note that this string must be a complete self-contained graph, with its inputs and outputs explicitly defined. For example if your command line is of the form: <pre class="example-preformatted">ffmpeg -i infile -vf scale=640:360 outfile </pre> your <var class="var">GRAPH_DESCRIPTION</var> string will need to be of the form: <pre class="example-preformatted">nullsrc,scale=640:360,nullsink </pre> you may also need to set the <var class="var">nullsrc</var> parameters and add a <var class="var">format</var> filter in order to simulate a specific input file.

 <h2 class="chapter">4 Filtergraph description# TOC</h2>

A filtergraph is a directed graph of connected filters. It can contain cycles, and there can be multiple links between a pair of filters. Each link has one input pad on one side connecting it to one filter from which it takes its input, and one output pad on the other side connecting it to one filter accepting its output. Each filter in a filtergraph is an instance of a filter class registered in the application, which defines the features and the number of input and output pads of the filter. A filter with no input pads is called a "source", and a filter with no output pads is called a "sink". <h3 class="section">4.1 Filtergraph syntax# TOC</h3>

A filtergraph has a textual representation, which is recognized by the <samp class="option">-filter</samp>/<samp class="option">-vf</samp>/<samp class="option">-af</samp> and <samp class="option">-filter_complex</samp> options in <code class="command">ffmpeg</code> and <samp class="option">-vf</samp>/<samp class="option">-af</samp> in <code class="command">ffplay</code>, and by the <code class="code">avfilter_graph_parse_ptr()</co function defined in <samp class="file">libavfilter/avfilter.h</samp>. A filterchain consists of a sequence of connected filters, each one connected to the previous one in the sequence. A filterchain is represented by a list of ","-separated filter descriptions. A filtergraph consists of a sequence of filterchains. A sequence of filterchains is represented by a list of ";"-separated filterchain descriptions. A filter is represented by a string of the form: [<var class="var">in_link_1</var>]...[<var class="var">in_link_N</var>]<var class="var">filter_name</var>@<var class="var">id</var>=<var class="var">arguments</var>[<var class="var">out_link_1</var>]...[<var

class=”var”>out_link_M</var>] <var class=”var”>filter_name</var> is the name of the filter class of which the described filter is an instance of, and has to be the name of one of the filter classes registered in the program optionally followed by "@<var class=”var”>id</var>". The name of the filter class is optionally followed by a string "=<var class=”var”>arguments</var>". <var class=”var”>arguments</var> is a string which contains the parameters used to initialize the filter instance. It may have one of two forms: <ul class=”itemize mark-bullet”> A ’:’-separated list of <var class=”var”>key=value</var> pairs.

A ’:’-separated list of <var class=”var”>value</var>. In this case, the keys are assumed to be the option names in the order they are declared. E.g. the <code class=”code”>fade</code> filter declares three options in this order – <samp class=”option”>type</samp>, <samp class=”option”>start_frame</samp> and <samp class=”option”>nb_frames</samp>. Then the parameter list <var class=”var”>in:0:30</var> means that the value <var class=”var”>in</var> is assigned to the option <samp class=”option”>type</samp>, <var class=”var”>0</var> to <samp class=”option”>start_frame</samp> and <var class=”var”>30</var> to <samp class=”option”>nb_frames</samp>.

A ’:’-separated list of mixed direct <var class=”var”>value</var> and long <var class=”var”>key=value</var> pairs. The direct <var class=”var”>value</var> must precede the <var class=”var”>key=value</var> pairs, and follow the same constraints order of the previous point. The following <var class=”var”>key=value</var> pairs can be set in any preferred order.

If the option value itself is a list of items (e.g. the <code class=”code”>format</code> filter takes a list of pixel formats), the items in the list are usually separated by ‘<samp class=”samp”>|</samp>’. The list of arguments can be quoted using the character ‘<samp class=”samp”>'</samp>’ as initial and ending mark, and the character ‘<samp class=”samp”>\</samp>’ for escaping the characters within the quoted text; otherwise the argument string is considered terminated when the next special character (belonging to the set ‘<samp class=”samp”>[]=;,</samp>’) is encountered. A special syntax implemented in the <code class=”command”>ffmpeg</code> CLI tool allows loading option values from files. This is done be prepending a slash ’/’ to the option name, then the supplied value is interpreted as a path from which the actual value is loaded. E.g. <pre class=”example-preformatted”>ffmpeg -i <INPUT> -vf drawtext=/text=/tmp/some_text <OUTPUT> </pre> will load the text to be drawn from <samp class=”file”>/tmp/some_text</samp>. API users wishing to implement a similar feature should use the <code class=”code”>avfilter_graph_segment_*()</code> functions together with custom IO code. The name and arguments of the fil-

ter are optionally preceded and followed by a list of link labels. A link label allows one to name a link and associate it to a filter output or input pad. The preceding labels <var class=”var”>in_link_1</var> ... <var class=”var”>in_link_N</var>, are associated to the filter input pads, the following labels <var class=”var”>out_link_1</var> ... <var class=”var”>out_link_M</var>, are associated to the output pads. When two link labels with the same name are found in the filtergraph, a link between the corresponding input and output pad is created. If an output pad is not labelled, it is linked by default to the first unlabelled input pad of the next filter in the filterchain. For example in the filterchain <pre class=”example-preformatted”>nullsrc, split[L1], [L2]overlay, nullsink </pre> the split filter instance has two output pads, and the overlay filter instance two input pads. The first output pad of split is labelled "L1", the first input pad of overlay is labelled "L2", and the second output pad of split is linked to the second input pad of overlay, which are both unlabelled. In a filter description, if the input label of the first filter is not specified, "in" is assumed; if the output label of the last filter is not specified, "out" is assumed. In a complete filterchain all the unlabelled filter input and output pads must be connected. A filtergraph is considered valid if all the filter input and output pads of all the filterchains are connected. Leading and trailing whitespaces (space, tabs, or line feeds) separating tokens in the filtergraph specification are ignored. This means that the filtergraph can be expressed using empty lines and spaces to improve readability. For example, the filtergraph: <pre class=”example-preformatted”>testsrc,split[L1],hflip[L2];[L1][L2] hstack </pre>

can be represented as: <pre class=”example-preformatted”>testsrc, split [L1], hflip [L2];

[L1][L2] hstack </pre>

Libavfilter will automatically insert scale filters where format conversion is required. It is possible to specify swscale flags for those automatically inserted scalers by prepending <code class=”code”>sws_flags=<var class=”var”>flags</var>;</code> to the filtergraph description. Here is a BNF description of the filtergraph syntax: <pre class=”example-preformatted”><var class=”var”>NAME</var> ::= sequence of alphanumeric characters and '_' <var class=”var”>FILTER_NAME</var> ::= <var class=”var”>NAME</var>["@"<var class=”var”>NAME</var>] <var class=”var”>LINKLABEL</var> ::= "[" <var class=”var”>NAME</var> "]" <var class=”var”>LINKLABELS</var> ::= <var class=”var”>LINKLABEL</var> [<var class=”var”>LINKLABELS</var>] <var class=”var”>FILTER_ARGUMENTS</var> ::= sequence of chars (possibly quoted) <var class=”var”>FILTER</var> ::= [<var class=”var”>LINKLABELS</var>] <var class=”var”>FILTER_NAME</var>

["=" <var class="var">FILTER_ARGUMENTS</var>] [<var class="var">LINKLABELS</var>] <var class="var">FILTERCHAIN</var> ::= <var class="var">FILTER</var> [,<var class="var">FILTERCHAIN</var>] <var class="var">FILTERGRAPH</var> ::= [sws_flags=<var class="var">flags</var>;] <var class="var">FILTERCHAIN</var> [;<var class="var">FILTERGRAPH</var>] </pre>

 <h3 class="section">4.2 Notes on filtergraph escaping# TOC</h3>

Filtergraph description composition entails several levels of escaping. See <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#quoting_005fand_005fescaping">the "Quoting and escaping" section in the ffmpeg-utils(1) manual for more information about the employed escaping procedure. A first level escaping affects the content of each filter option value, which may contain the special character <code class="code">:</code> used to separate values, or one of the escaping characters <code class="code">\'</code>. A second level escaping affects the whole filter description, which may contain the escaping characters <code class="code">\'</code> or the special characters <code class="code">[],;</code> used by the filtergraph description. Finally, when you specify a filtergraph on a shell commandline, you need to perform a third level escaping for the shell special characters contained within it. For example, consider the following string to be embedded in the drawtext filter description <samp class="option">text</samp> value: <pre class="example-preformatted">this is a 'string': may contain one, or more, special characters </pre>

This string contains the <code class="code">'</code> special escaping character, and the <code class="code">:</code> special character, so it needs to be escaped in this way: <pre class="example-preformatted">text=this is a \'string\'\: may contain one, or more, special characters </pre>

A second level of escaping is required when embedding the filter description in a filtergraph description, in order to escape all the filtergraph special characters. Thus the example above becomes: <pre class="example-preformatted">drawtext=text=this is a \\\'string\\\'\\: may contain one\, or more\, special characters </pre> (note that in addition to the <code class="code">\'</code> escaping special characters, also <code class="code">,</code> needs to be escaped). Finally an additional level of escaping is needed when writing the filtergraph description in a shell command, which depends on the escaping rules of the adopted shell. For example, assuming that <code class="code">\</code> is special and

needs to be escaped with another <code class=”code”>\</code>, the previous string will finally result in: <pre class=”example-preformatted”>-vf "drawtext=text=this is a \\\\\\'string\\\\\\'\\\\: may contain one\\, or more\\, special characters" </pre>

In order to avoid cumbersome escaping when using a commandline tool accepting a filter specification as input, it is advisable to avoid direct inclusion of the filter or options specification in the shell. For example, in case of the drawtext filter, you might prefer to use the <samp class=”option”>textfile</samp> option in place of <samp class=”option”>text</samp> to specify the text to render. <h2 class=”chapter”>5 Timeline editing# TOC</h2>

Some filters support a generic <samp class=”option”>enable</samp> option. For the filters supporting timeline editing, this option can be set to an expression which is evaluated before sending a frame to the filter. If the evaluation is non-zero, the filter will be enabled, otherwise the frame will be sent unchanged to the next filter in the filtergraph. The expression accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>t</samp>’</dt> <dd> timestamp expressed in seconds, NAN if the input timestamp is unknown </dd> <dt>‘<samp class=”samp”>n</samp>’</dt> <dd> sequential number of the input frame, starting from 0 </dd> <dt>‘<samp class=”samp”>pos</samp>’</dt> <dd> the position in the file of the input frame, NAN if unknown; deprecated, do not use </dd> <dt>‘<samp class=”samp”>w</samp>’</dt> <dt>‘<samp class=”samp”>h</samp>’</dt> <dd> width and height of the input frame if video </dd> </dl>

Additionally, these filters support an <samp class=”option”>enable</samp> command that can be used to re-define the expression. Like any other filtering option, the <samp class=”option”>enable</samp> option follows the same rules. For example, to enable a blur filter (smartblur) from 10 seconds to 3 minutes, and a curves filter starting at 3 seconds: <pre class=”example-preformatted”>smartblur = enable='between(t,10,3*60)', curves = enable='gte(t,3)' : preset=cross_process </pre>

See <code class=”code”>ffmpeg -filters</code> to view which filters have timeline support.

 <h2 class=”chapter”>6 Changing options at runtime with a command<a class=”anchor

hidden-xs" href="#Changing-options-at-runtime-with-a-command" aria-hidden="true"># TOC</h2>

Some options can be changed during the operation of the filter using a command. These options are marked ’T’ on the output of <code class="command">ffmpeg</code> <samp class="option">-h filter=<name of filter></samp>. The name of the command is the name of the option and the argument is the new value. <h2 class="chapter">7 Options for filters with several inputs (framesync)# TOC</h2>

Some filters with several inputs support a common set of options. These options can only be set by name, not with the short notation. <dl class="table"> <dt><samp class="option">eof_action</samp></dt> <dd> The action to take when EOF is encountered on the secondary input; it accepts one of the following values: <dl class="table"> <dt><samp class="option">repeat</samp></dt> <dd> Repeat the last frame (the default). </dd> <dt><samp class="option">endall</samp></dt> <dd> End both streams. </dd> <dt><samp class="option">pass</samp></dt> <dd> Pass the main input through. </dd> </dl>

</dd> <dt><samp class="option">shortest</samp></dt> <dd> If set to 1, force the output to terminate when the shortest input terminates. Default value is 0. </dd> <dt><samp class="option">repeatlast</samp></dt> <dd> If set to 1, force the filter to extend the last frame of secondary streams until the end of the primary stream. A value of 0 disables this behavior. Default value is 1. </dd> <dt><samp class="option">ts_sync_mode</samp></dt> <dd> How strictly to sync streams based on secondary input timestamps; it accepts one of the following values: <dl class="table"> <dt><samp class="option">default</samp></dt> <dd> Frame from secondary input with the nearest lower or equal timestamp to the primary input frame. </dd> <dt><samp class="option">nearest</samp></dt> <dd> Frame from secondary input with the absolute nearest timestamp to the primary input frame. </dd> </dl> </dd> </dl>

 <h2 class="chapter">8 Audio Filters# TOC</h2>

When you configure your FFmpeg build, you can disable any of the existing

filters using <code class=”code”>--disable-filters</code>. The configure output will show the audio filters included in your build. Below is a description of the currently available audio filters. <h3 class=”section”>8.1 aap# TOC</h3> Apply Affine Projection algorithm to the first audio stream using the second audio stream. This adaptive filter is used to estimate unknown audio based on multiple input audio samples. Affine projection algorithm can make trade-offs between computation complexity with convergence speed. A description of the accepted options follows. <dl class=”table”> <dt><samp class=”option”>order</samp></dt> <dd> Set the filter order. </dd> <dt><samp class=”option”>projection</samp></dt> <dd> Set the projection order. </dd> <dt><samp class=”option”>mu</samp></dt> <dd> Set the filter mu. </dd> <dt><samp class=”option”>delta</samp></dt> <dd> Set the coefficient to initialize internal covariance matrix. </dd> <dt><samp class=”option”>out_mode</samp></dt> <dd> Set the filter output samples. </dd> <dt><samp class=”option”>precision</samp></dt> <dd> Set which precision to use when processing samples. <dl class=”table”> <dt><samp class=”option”>auto</samp></dt> <dd> Auto pick internal sample format depending on other filters. </dd> <dt><samp class=”option”>float</samp></dt> <dd> Always use single-floating point precision sample format. </dd> <dt><samp class=”option”>double</samp></dt> <dd> Always use double-floating point precision sample format. </dd> </dl> </dd> </dl>

 <h3 class=”section”>8.2 acompressor# TOC</h3>

A compressor is mainly used to reduce the dynamic range of a signal. Especially modern music is mostly compressed at a high ratio to improve the overall loudness. It’s done to get the highest attention of a listener, "fatten" the sound and bring more "power" to the track. If a signal is compressed too much it may sound dull or "dead"

afterwards or it may start to "pump" (which could be a powerful effect but can also destroy a track completely). The right compression is the key to reach a professional sound and is the high art of mixing and mastering. Because of its complex settings it may take a long time to get the right feeling for this kind of effect. Compression is done by detecting the volume above a chosen level <code class="code">threshold</code> and dividing it by the factor set with <code class="code">ratio</code>. So if you set the threshold to -12dB and your signal reaches -6dB a ratio of 2:1 will result in a signal at -9dB. Because an exact manipulation of the signal would cause distortion of the waveform the reduction can be levelled over the time. This is done by setting "Attack" and "Release". <code class="code">attack</code> determines how long the signal has to rise above the threshold before any reduction will occur and <code class="code">release</code> sets the time the signal has to fall below the threshold to reduce the reduction again. Shorter signals than the chosen attack time will be left untouched. The overall reduction of the signal can be made up afterwards with the <code class="code">makeup</code> setting. So compressing the peaks of a signal about 6dB and raising the makeup to this level results in a signal twice as loud than the source. To gain a softer entry in the compression the <code class="code">knee</code> flattens the hard edge at the threshold in the range of the chosen decibels. The filter accepts the following options: <dl class="table"> <dt><samp class="option">level_in</samp></dt> <dd> Set input gain. Default is 1. Range is between 0.015625 and 64. </dd> <dt><samp class="option">mode</samp></dt> <dd> Set mode of compressor operation. Can be <code class="code">upward</code> or <code class="code">downward</code>. Default is <code class="code">downward</code>. </dd> <dt><samp class="option">threshold</samp></dt> <dd> If a signal of stream rises above this level it will affect the gain reduction. By default it is 0.125. Range is between 0.00097563 and 1. </dd> <dt><samp class="option">ratio</samp></dt> <dd> Set a ratio by which the signal is reduced. 1:2 means that if the level rose 4dB above the threshold, it will be only 2dB above after the reduction. Default is 2. Range is between 1 and 20. </dd> <dt><samp class="option">attack</samp></dt> <dd> Amount of milliseconds the signal has to rise above the threshold before gain reduction starts. Default is 20. Range is between 0.01 and 2000. </dd> <dt><samp class="option">release</samp></dt> <dd> Amount of milliseconds the signal has to fall below the threshold before reduction is decreased again. Default is 250. Range is between 0.01 and 9000. </dd> <dt><samp class="option">makeup</samp></dt> <dd> Set the amount by how much signal will be amplified after processing. Default is 1. Range is from 1 to 64. </dd> <dt><samp class="option">knee</samp></dt> <dd> Curve the sharp knee around the threshold to enter gain reduction more softly. Default is 2.82843. Range is between 1 and 8. </dd> <dt><samp class="option">link</samp></dt> <dd> Choose

if the <code class="code">average</code> level between all channels of input stream or the louder(<code class="code">maximum</code>) channel of input stream affects the reduction. Default is <code class="code">average</code>. </dd> <dt><samp class="option">detection</samp></dt> <dd> Should the exact signal be taken in case of <code class="code">peak</code> or an RMS one in case of <code class="code">rms</code>. Default is <code class="code">rms</code> which is mostly smoother. </dd> <dt><samp class="option">mix</samp></dt> <dd> How much to use compressed signal in output. Default is 1. Range is between 0 and 1. </dd> </dl>

 <h4 class="subsection">8.2.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">8.3 acontrast# TOC</h3> Simple audio dynamic range compression/expansion filter. The filter accepts the following options: <dl class="table"> <dt><samp class="option">contrast</samp></dt> <dd> Set contrast. Default is 33. Allowed range is between 0 and 100. </dd> </dl>

 <h3 class="section">8.4 acopy# TOC</h3>

Copy the input audio source unchanged to the output. This is mainly useful for testing purposes. <h3 class="section">8.5 acrossfade# TOC</h3>

Apply cross fade from one input audio stream to another input audio stream. The cross fade is applied for specified duration near the end of first stream. The filter accepts the following options: <dl class="table"> <dt><samp class="option">inputs, n</samp></dt> <dd> Specify the number of inputs to crossfade. When crossfading multiple inputs, each input will be concatenated and crossfaded in sequence, similar to the concat filter. Default is 2. </dd> <dt><samp class="option">nb_samples, ns</samp></dt> <dd> Specify the number of samples for which the cross fade effect has to last. At the end of the cross fade effect the first input audio will be completely silent. Default is 44100. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Specify

the duration of the cross fade effect. See <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#time-duration-syntax">the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. By default the duration is determined by <var class="var">nb_samples</var>. If set this option is used instead of <var class="var">nb_samples</var>. </dd> <dt><samp class="option">overlap, o</samp></dt> <dd> Should first stream end overlap with second stream start. Default is enabled. </dd> <dt><samp class="option">curve1</samp></dt> <dd> Set curve for cross fade transition for first stream. </dd> <dt><samp class="option">curve2</samp></dt> <dd> Set curve for cross fade transition for second stream. For description of available curve types see afade filter description. </dd> </dl>

 <h4 class="subsection">8.5.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Cross fade from one input to another: <pre class="example-preformatted">ffmpeg -i first.flac -i second.flac -filter_complex acrossfade=d=10:c1=exp:c2=exp output.flac </pre>

Cross fade from one input to another but without overlapping: <pre class="example-preformatted">ffmpeg -i first.flac -i second.flac -filter_complex acrossfade=d=10:o=0:c1=exp:c2=exp output.flac </pre>

Concatenate multiple inputs with cross fade between each: <pre class="example-preformatted">ffmpeg -i first.flac -i second.flac -i third.flac -filter_complex acrossfade=n=3 output.flac </pre>

 <h3 class="section">8.6 acrossover# TOC</h3> Split audio stream into several bands. This filter splits audio stream into two or more frequency ranges. Summing all streams back will give flat output. The filter accepts the following options: <dl class="table"> <dt><samp class="option">split</samp></dt> <dd> Set split frequencies. Those must be positive and increasing. </dd> <dt><samp class="option">order</samp></dt> <dd> Set filter order for each band split. This controls filter roll-off or steepness of filter transfer function.  <h3 class="section">8.7 acrusher<span

class=”pull-right”># TOC</h3>

Reduce audio bit resolution. This filter is bit crusher with enhanced functionality. A bit crusher is used to audibly reduce number of bits an audio signal is sampled with. This doesn’t change the bit depth at all, it just produces the effect. Material reduced in bit depth sounds more harsh and "digital". This filter is able to even round to continuous values instead of discrete bit depths. Additionally it has a D/C offset which results in different crushing of the lower and the upper half of the signal. An Anti-Aliasing setting is able to produce "softer" crushing sounds. Another feature of this filter is the logarithmic mode. This setting switches from linear distances between bits to logarithmic ones. The result is a much more "natural" sounding crusher which doesn’t gate low signals for example. The human ear has a logarithmic perception, so this kind of crushing is much more pleasant. Logarithmic crushing is also able to get anti-aliased. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>level_in</samp></dt> <dd> Set level in. </dd> <dt><samp class=”option”>level_out</samp></dt> <dd> Set level out. </dd> <dt><samp class=”option”>bits</samp></dt> <dd> Set bit reduction. </dd> <dt><samp class=”option”>mix</samp></dt> <dd> Set mixing amount. </dd> <dt><samp class=”option”>mode</samp></dt> <dd> Can be linear: <code class=”code”>lin</code> or logarithmic: <code class=”code”>log</code>. </dd> <dt><samp class=”option”>dc</samp></dt> <dd> Set DC. </dd> <dt><samp class=”option”>aa</samp></dt> <dd> Set anti-aliasing. </dd> <dt><samp class=”option”>samples</samp></dt> <dd> Set sample reduction. </dd> <dt><samp class=”option”>lfo</samp></dt> <dd> Enable LFO.  <h3 class=”section”>8.25 afir# TOC</h3>

Apply an arbitrary Finite Impulse Response filter.

This filter is designed for applying long FIR filters,

up to 60 seconds long.

It can be used as component for digital crossover filters,

room equalization, cross talk cancellation, wavefield synthesis,

auralization, ambiophonics, ambisonics and spatialization.

This filter uses the streams higher than first one as FIR coefficients.

If the non-first stream holds a single channel, it will be used

for all input channels in the first stream, otherwise

the number of channels in the non-first stream must be same as

the number of channels in the first stream.

It accepts the following parameters:

<dl class="table">

<dt><samp class="option">dry</samp></dt>

<dd> Set dry gain. This sets input gain.

</dd>

<dt><samp class="option">wet</samp></dt>

<dd> Set wet gain. This sets final output gain.

</dd>

<dt><samp class="option">length</samp></dt>

<dd> Set Impulse Response filter length. Default is 1, which means whole IR is processed.

</dd>

<dt><samp class="option">gtype</samp></dt>

<dd> This option is deprecated, and does nothing.

</dd>

<dt><samp class="option">irnorm</samp></dt>

<dd> Set norm to be applied to IR coefficients before filtering.

Allowed range is from <var class="var">-1</var> to <var class="var">2</var>.

IR coefficients are normalized with calculated vector norm set by this option.

For negative values, no norm is calculated, and IR coefficients are not modified at all.

Default is <var class="var">1</var>.

</dd>

<dt><samp class="option">irlink</samp></dt>

<dd> For multichannel IR if this option is set to <var class="var">true</var>, all IR channels will be

normalized with maximal measured gain of all IR channels coefficients as set by <code class="code">irnorm</code> option.

When disabled, all IR coefficients in each IR channel will be normalized independently.

Default is <var class="var">true</var>.

</dd>

<dt><samp class="option">irgain</samp></dt>

<dd> Set gain to be applied to IR coefficients before filtering.

Allowed range is 0 to 1. This gain is applied after any gain applied with <var class="var">irnorm</var> option.

</dd>

<dt><samp class="option">irfmt</samp></dt>

<dd> Set format of IR stream. Can be <code class="code">mono</code> or <code class="code">input</code>.

Default is <code class="code">input</code>.

</dd>

<dt><samp class="option">maxir</samp></dt>

<dd> Set max allowed Impulse Response filter duration in seconds. Default is 30 seconds.

Allowed range is 0.1 to 60 seconds.

</dd>

<dt><samp class="option">response</samp></dt>

<dd> This option is deprecated, and does nothing.

 <h3 class="section">8.34 amerge# TOC</h3>

Merge two or more audio streams into a single multi-channel stream. All inputs must have the same sample rate, and format. If inputs do not have the same duration, the output will stop with the shortest. The filter accepts the following options: <dl class="table"> <dt><samp class="option">inputs</samp></dt> <dd> Set the number of inputs. Default is 2. </dd> <dt><samp class="option">layout_mode</samp></dt> <dd> This option controls how the output channel layout is determined and if the audio channels are reordered during merge. <dl class="table"> <dt><samp class="option">legacy</samp></dt> <dd> This is the mode how the filter behaved historically so it is the default. If the channel layouts of the inputs are known and disjoint, and therefore compatible, the channel layout of the output will be set accordingly and the channels will be reordered as necessary. If the channel layouts of the inputs are not disjoint, some of them are unknown, or they are using special channel layouts, such as ambisonics, the output will have all the channels of the first input then all the channels of the second input, in that order, and the channel layout

of the output will be the default value corresponding to the total number of channels. For example, if the first input is in 2.1 (FL+FR+LF) and the second input is FC+BL+BR, then the output will be in 5.1, with the channels in the following order: a1, a2, b1, a3, b2, b3 (a1 is the first channel of the first input, b1 is the first channel of the second input). On the other hand, if both input are in stereo, the output channels will be in the default order: a1, a2, b1, b2, and the channel layout will be arbitrarily set to 4.0, which may or may not be the expected value. </dd> <dt><samp class="option">reset</samp></dt> <dd> This mode ignores the input channel layouts and does no channel reordering. The output will have all the channels of the first input, then all the channels of the second input, in that order, and so on. The output channel layout will only specify the total channel count. </dd> <dt><samp class="option">normal</samp></dt> <dd> This mode keeps channel name and designation information from the input channels and does no channel reordering. The output will have all the channels of the first input, then all the channels of the second input, in that order, and so on. </dd> </dl>

</dd> </dl>

 <h4 class="subsection">8.34.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Merge two mono files into a stereo stream: <pre class="example-preformatted">amovie=left.wav [l] ; amovie=right.mp3 [r] ; [l] [r] amerge </pre>

Multiple merges assuming 1 video stream and 6 audio streams in <samp class="file">input.mkv</samp>: <pre class="example-preformatted">ffmpeg -i input.mkv -filter_complex "[0:1][0:2][0:3][0:4][0:5][0:6] amerge=inputs=6" -c:a pcm_s16le output.mkv </pre>

 <h3 class="section">8.35 amix# TOC</h3>

Mixes multiple audio inputs into a single output. Note that this filter only supports float samples (the <var class="var">amerge</var> and <var class="var">pan</var> audio filters support many formats). If the <var class="var">amix</var> input has integer samples then aresample will be automatically inserted to perform the conversion to float samples. It accepts the following parameters: <dl class="table"> <dt><samp class="option">inputs</samp></dt> <dd> The number of inputs. If unspecified, it defaults to 2. </dd> <dt><samp class="option">duration</samp></dt> <dd> How to determine the end-of-stream. <dl class="table"> <dt><samp

class=”option”>longest</samp></dt> <dd> The duration of the longest input. (default) </dd> <dt><samp class=”option”>shortest</samp></dt> <dd> The duration of the shortest input. </dd> <dt><samp class=”option”>first</samp></dt> <dd> The duration of the first input. </dd> </dl>

</dd> <dt><samp class=”option”>dropout_transition</samp></dt> <dd> The transition time, in seconds, for volume renormalization when an input stream ends. The default value is 2 seconds. </dd> <dt><samp class=”option”>weights</samp></dt> <dd> Specify weight of each input audio stream as a sequence of numbers separated by a space. If fewer weights are specified compared to number of inputs, the last weight is assigned to the remaining inputs. Default weight for each input is 1. </dd> <dt><samp class=”option”>normalize</samp></dt> <dd> Always scale inputs instead of only doing summation of samples. Beware of heavy clipping if inputs are not normalized prior or after filtering by this filter if this option is disabled. By default is enabled. </dd> </dl>

 <h4 class=”subsection”>8.35.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> This will mix 3 input audio streams to a single output with the same duration as the first input and a dropout transition time of 3 seconds: <pre class=”example-preformatted”>ffmpeg -i INPUT1 -i INPUT2 -i INPUT3 -filter_complex amix=inputs=3:duration=first:dropout_transition=3 OUTPUT </pre>

This will mix one vocal and one music input audio stream to a single output with the same duration as the longest input. The music will have quarter the weight as the vocals, and the inputs are not normalized: <pre class=”example-preformatted”>ffmpeg -i VOCALS -i MUSIC -filter_complex amix=inputs=2:duration=longest:dropout_transition=0:weights="1 0.25":normalize=0 OUTPUT </pre>

 <h4 class=”subsection”>8.35.2 Commands# TOC</h4>

This filter supports the following commands: <dl class=”table”> <dt><samp class=”option”>weights</samp></dt> <dt><samp class=”option”>normalize</samp></dt> <dd> Syntax is same as option with same name. </dd> </dl>

Allowed range is from 0 to 1. </dd> <dt><samp class="option">iterations</samp></dt> <dd> Set number of iterations of psychoacoustic clipper. Allowed range is from 1 to 20. Default value is 10. </dd> <dt><samp class="option">level</samp></dt> <dd> Auto level output signal. Default is disabled. This normalizes audio back to 0dBFS if enabled. </dd> </dl>

 <h4 class="subsection">8.45.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">8.46 apulsator# TOC</h3>

Audio pulsator is something between an autopanner and a tremolo. But it can produce funny stereo effects as well. Pulsator changes the volume of the left and right channel based on a LFO (low frequency oscillator) with different waveforms and shifted phases. This filter have the ability to define an offset between left and right channel. An offset of 0 means that both LFO shapes match each other. The left and right channel are altered equally - a conventional tremolo. An offset of 50% means that the shape of the right channel is exactly shifted in phase (or moved backwards about half of the frequency) - pulsator acts as an autopanner. At 1 both curves match again. Every setting in between moves the phase shift gapless between all stages and produces some "bypassing" sounds with sine and triangle waveforms. The more you set the offset near 1 (starting from the 0.5) the faster the signal passes from the left to the right speaker. The filter accepts the following options: <dl class="table"> <dt><samp class="option">level_in</samp></dt> <dd> Set input gain. By default it is 1. Range is [0.015625 - 64]. </dd> <dt><samp class="option">level_out</samp></dt> <dd> Set output gain. By default it is 1. Range is [0.015625 - 64]. </dd> <dt><samp class="option">mode</samp></dt> <dd> Set waveform shape the LFO will use. Can be one of: sine, triangle, square, sawup or sawdown. Default is sine. </dd> <dt><samp class="option">amount</samp></dt> <dd> Set modulation. Define how much of original signal is affected by the LFO. </dd> <dt><samp class="option">offset_l</samp></dt>

<dd> Set left channel offset. Default is 0. Allowed range is [0 - 1]. </dd> <dt><samp class="option">offset_r</samp></dt> <dd> Set right channel offset. Default is 0.5.  <h4 class="subsection">8.66.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">8.67 atrim# TOC</h3>

Trim the input so that the output contains one continuous subpart of the input. It accepts the following parameters: <dl class="table"> <dt><samp class="option">start</samp></dt> <dd> Timestamp (in seconds) of the start of the section to keep. I.e. the audio sample with the timestamp <var class="var">start</var> will be the first sample in the output. </dd> <dt><samp class="option">end</samp></dt> <dd> Specify time of the first audio sample that will be dropped,

i.e. the audio sample immediately preceding the one with the timestamp <var class="var">end</var> will be the last sample in the output. </dd> <dt><samp class="option">start_pts</samp></dt> <dd> Same as <var class="var">start</var>, except this option sets the start timestamp in samples instead of seconds. </dd> <dt><samp class="option">end_pts</samp></dt> <dd> Same as <var class="var">end</var>, except this option sets the end timestamp in samples instead of seconds. </dd> <dt><samp class="option">duration</samp></dt> <dd> The maximum duration of the output in seconds. </dd> <dt><samp class="option">start_sample</samp></dt> <dd> The number of the first sample that should be output. </dd> <dt><samp class="option">end_sample</samp></dt> <dd> The number of the first sample that should be dropped. </dd> </dl>

<samp class="option">start</samp>, <samp class="option">end</samp>, and <samp class="option">duration</samp> are expressed as time duration specifications; see <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#time-duration-syntax">the Time duration section in the ffmpeg-utils(1) manual. Note that the first two sets of the start/end options and the <samp class="option">duration</samp> option look at the frame timestamp, while the _sample options simply count the samples that pass through the filter. So start/end_pts and start/end_sample will give different results when the timestamps are wrong, inexact or do not start at zero. Also note that this filter does not modify the timestamps. If you wish to have the output timestamps start at zero, insert the asetpts filter after the atrim filter. If multiple start or end options are set, this filter tries to be greedy and keep all samples that match at least one of the specified constraints. To keep only the part that matches all the constraints at once, chain multiple atrim filters. The defaults are such that all the input is kept. So it is possible to set e.g. just the end values to keep everything before the specified time. Examples: <ul class="itemize mark-bullet"> Drop everything except the second minute of input: <pre class="example-preformatted">ffmpeg -i INPUT -af atrim=60:120 </pre>

Keep only the first 1000 samples: <pre class="example-preformatted">ffmpeg -i INPUT -af atrim=end_sample=1000 </pre>

 <h3 class="section">8.68 axcorrelate# TOC</h3> Calculate normalized windowed cross-correlation between two input audio streams. Resulted samples are always between -1 and 1 inclusive. If result is 1 it means two input samples are highly correlated in that selected

segment. Result 0 means they are not correlated at all. If result is -1 it means two input samples are out of phase, which means they cancel each other. The filter accepts the following options: <dl class="table"> <dt><samp class="option">size</samp></dt> <dd> Set size of segment over which cross-correlation is calculated. Default is 256. Allowed range is from 2 to 131072. </dd> <dt><samp class="option">algo</samp></dt> <dd> Set algorithm for cross-correlation. Can be <code class="code">slow</code> or <code class="code">fast</code> or <code class="code">best</code>. Default is <code class="code">best</code>. Fast algorithm assumes mean values over any given segment are always zero and thus need much less calculations to make. This is generally not true, but is valid for typical audio streams. </dd> </dl>

 <h4 class="subsection">8.68.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Calculate correlation between channels in stereo audio stream: <pre class="example-preformatted">ffmpeg -i stereo.wav -af channelsplit,axcorrelate=size=1024:algo=fast correlation.wav </pre>

 <h3 class=”section”>8.78 compensationdelay# TOC</h3>

Compensation Delay Line is a metric based delay to compensate differing positions of microphones or speakers. For example, you have recorded guitar with two microphones placed in different locations. Because the front of sound wave has fixed speed in normal conditions, the phasing of microphones can vary and depends on their location and interposition. The best sound mix can be achieved when these microphones are in phase (synchronized). Note that a distance of ~30 cm between microphones makes one microphone capture the signal in antiphase to the other microphone. That makes the final mix sound moody. This filter helps to solve phasing problems by adding different delays to each microphone track and make them synchronized. The best result can be reached when you take one track as base and synchronize other tracks one by one with it. Remember that synchronization/delay tolerance depends on sample rate, too. Higher sample rates will give more tolerance. The filter accepts the following parameters: <dl class="table"> <dt><samp class="option">mm</samp></dt> <dd> Set millimeters distance. This is compensation distance for fine tuning. Default is 0. </dd> <dt><samp class="option">cm</samp></dt> <dd> Set cm distance. This is compensation distance for tightening distance setup. <h3 class="section">8.85 dynaudnorm# TOC</h3>

Dynamic Audio Normalizer.

This filter applies a certain amount of gain to the input audio in order

to bring its peak magnitude to a target level (e.g. 0 dBFS). However, in

contrast to more "simple" normalization algorithms, the Dynamic Audio

Normalizer *dynamically* re-adjusts the gain factor to the input audio.

This allows for applying extra gain to the "quiet" sections of the audio

while avoiding distortions or clipping the "loud" sections. In other words:

The Dynamic Audio Normalizer will "even out" the volume of quiet and loud

sections, in the sense that the volume of each section is brought to the

same target level. Note, however, that the Dynamic Audio Normalizer achieves

this goal *without* applying "dynamic range compressing". It will retain 100%

of the dynamic range *within* each section of the audio file.

<dl class="table">

<dt><samp class="option">framelen, f</samp></dt>

<dd> Set the frame length in milliseconds. In range from 10 to 8000 milliseconds.

Default is 500 milliseconds.

The Dynamic Audio Normalizer processes the input audio in small chunks,

referred to as frames. This is required, because a peak magnitude has no

meaning for just a single sample value. Instead, we need to determine the

peak magnitude for a contiguous sequence of sample values. While a "standard"

normalizer would simply use the peak magnitude of the complete file, the

Dynamic Audio Normalizer determines the peak magnitude individually for each

frame. The length of a frame is specified in milliseconds. By default, the

Dynamic Audio Normalizer uses a frame length of 500 milliseconds, which has

been found to give good results with most files.

Note that the exact frame length, in number of samples, will be determined

automatically, based on the sampling rate of the individual input audio file.

</dd>

<dt><samp class="option">gausssize, g</samp></dt>

<dd> Set the Gaussian filter window size. In range from 3 to 301, must be odd

number. Default is 31.

Probably the most important parameter of the Dynamic Audio Normalizer is the

<code class="code">window size</code> of the Gaussian smoothing filter. The filter’s window size

is specified in frames, centered around the current frame. For the sake of

simplicity, this must be an odd number. Consequently, the default value of 31

takes into account the current frame, as well as the 15 preceding frames and

the 15 subsequent frames. Using a larger window results in a stronger

smoothing effect and thus in less gain variation, i.e. slower gain

adaptation. Conversely, using a smaller window results in a weaker smoothing

effect and thus in more gain variation, i.e. faster gain adaptation.

In other words, the more you increase this value, the more the Dynamic Audio

Normalizer will behave like a "traditional" normalization filter. On the

contrary, the more you decrease this value, the more the Dynamic Audio

Normalizer will behave like a dynamic range compressor.

</dd>

<dt><samp class="option">peak, p</samp></dt>

<dd> Set the target peak value. This specifies the highest permissible magnitude

level for the normalized audio input. This filter will try to approach the

target peak magnitude as closely as possible, but at the same time it also

makes sure that the normalized signal will never exceed the peak magnitude.

A frame’s maximum local gain factor is imposed directly by the target peak

magnitude. The default value is 0.95 and thus leaves a headroom of 5%*.

It is not recommended to go above this value.

</dd>

<dt><samp class="option">maxgain, m</samp></dt>

<dd> Set the maximum gain factor. In range from 1.0 to 100.0. Default is 10.0.

The Dynamic Audio Normalizer determines the maximum possible (local) gain

factor for each input frame, i.e. the maximum gain factor that does not

result in clipping or distortion. The maximum gain factor is determined by

the frame’s highest magnitude sample. However, the Dynamic Audio Normalizer

additionally bounds the frame’s maximum gain factor by a predetermined

(global) maximum gain factor. This is done in order to avoid excessive gain

factors in "silent" or almost silent frames. By default, the maximum gain

factor is 10.0, For most inputs the default value should be sufficient and

it usually is not recommended to increase this value. Though, for input

with an extremely low overall volume level, it may be necessary to allow even

higher gain factors. Note, however, that the Dynamic Audio Normalizer does

not simply apply a "hard" threshold (i.e. cut off values above the threshold).

Instead, a "sigmoid" threshold function will be applied. This way, the

gain factors will smoothly approach the threshold value, but never exceed that

value.

</dd>

<dt><samp class="option">targetrms, r</samp></dt>

<dd> Set the target RMS. In range from 0.0 to 1.0. Default is 0.0 - disabled.

By default, the Dynamic Audio Normalizer performs "peak" normalization.

This means that the maximum local gain factor for each frame is defined

(only) by the frame’s highest magnitude sample. This way, the samples can

be amplified as much as possible without exceeding the maximum signal

level, i.e. without clipping. Optionally, however, the Dynamic Audio

Normalizer can also take into account the frame’s root mean square,

abbreviated RMS. In electrical engineering, the RMS is commonly used to

determine the power of a time-varying signal. It is therefore considered

that the RMS is a better approximation of the "perceived loudness" than

just looking at the signal’s peak magnitude. Consequently, by adjusting all

frames to a constant RMS value, a uniform "perceived loudness" can be

established. If a target RMS value has been specified, a frame’s local gain

factor is defined as the factor that would result in exactly that RMS value.

Note, however, that the maximum local gain factor is still restricted by the

frame’s highest magnitude sample, in order to prevent clipping.

</dd>

<dt><samp class="option">coupling, n</samp></dt>

<dd> Enable channels coupling. By default is enabled.

By default, the Dynamic Audio Normalizer will amplify all channels by the same

amount. This means the same gain factor will be applied to all channels, i.e.

the maximum possible gain factor is determined by the "loudest" channel.

However, in some recordings, it may happen that the volume of the different

channels is uneven, e.g. one channel may be "quieter" than the other one(s).

In this case, this option can be used to disable the channel coupling. This way,

the gain factor will be determined independently for each channel, depending

only on the individual channel’s highest magnitude sample. This allows for

harmonizing the volume of the different channels.

</dd>

<dt><samp class="option">correctdc, c</samp></dt>

<dd> Enable DC bias correction. By default is disabled.

An audio signal (in the time domain) is a sequence of sample values.

In the Dynamic Audio Normalizer these sample values are represented in the

-1.0 to 1.0 range, regardless of the original input format. Normally, the

audio signal, or "waveform", should be centered around the zero point.

That means if we calculate the mean value of all samples in a file, or in a

single frame, then the result should be 0.0 or at least very close to that

value. If, however, there is a significant deviation of the mean value from

0.0, in either positive or negative direction, this is referred to as a

DC bias or DC offset. Since a DC bias is clearly undesirable, the Dynamic

Audio Normalizer provides optional DC bias correction.

With DC bias correction enabled, the Dynamic Audio Normalizer will determine

the mean value, or "DC correction" offset, of each input frame and subtract

that value from all of the frame’s sample values which ensures those samples

are centered around 0.0 again. Also, in order to avoid "gaps" at the frame

boundaries, the DC correction offset values will be interpolated smoothly

between neighbouring frames.

</dd>

<dt><samp class="option">altboundary, b</samp></dt>

<dd> Enable alternative boundary mode. By default is disabled.

The Dynamic Audio Normalizer takes into account a certain neighbourhood

around each frame. This includes the preceding frames as well as the

subsequent frames. However, for the "boundary" frames, located at the very

beginning and at the very end of the audio file, not all neighbouring

frames are available. In particular, for the first few frames in the audio

file, the preceding frames are not known. And, similarly, for the last few

frames in the audio file, the subsequent frames are not known. Thus, the

question arises which gain factors should be assumed for the missing frames

in the "boundary" region. The Dynamic Audio Normalizer implements two modes

to deal with this situation. The default boundary mode assumes a gain factor

of exactly 1.0 for the missing frames, resulting in a smooth "fade in" and

"fade out" at the beginning and at the end of the input, respectively.

</dd>
<dt><samp class=”option”>compress, s</samp></dt>
<dd> Set the compress factor. In range from 0.0 to 30.0. Default is 0.0.
By default, the Dynamic Audio Normalizer does not apply "traditional"
compression. This means that signal peaks will not be pruned and thus the
full dynamic range will be retained within each local neighbourhood. However,
in some cases it may be desirable to combine the Dynamic Audio Normalizer’s
normalization algorithm with a more "traditional" compression.
For this purpose, the Dynamic Audio Normalizer provides an optional compression
(thresholding) function. If (and only if) the compression feature is enabled,
all input frames will be processed by a soft knee thresholding function prior
to the actual normalization process. Put simply, the thresholding function is
going to prune all samples whose magnitude exceeds a certain threshold value.
However, the Dynamic Audio Normalizer does not simply apply a fixed threshold
value. Instead, the threshold value will be adjusted for each individual
frame.
In general, smaller parameters result in stronger compression, and vice versa.
Values below 3.0 are not recommended, because audible distortion may appear.

</dd>
<dt><samp class=”option”>threshold, t</samp></dt>
<dd> Set the target threshold value. This specifies the lowest permissible
magnitude level for the audio input which will be normalized.
If input frame volume is above this value frame will be normalized.
Otherwise frame may not be normalized at all. The default value is set
to 0, which means all input frames will be normalized.
This option is mostly useful if digital noise is not wanted to be amplified.

</dd>

<dt><samp class=”option”>channels, h</samp></dt>

<dd> Specify which channels to filter, by default all available channels are filtered.

</dd>

<dt><samp class=”option”>overlap, o</samp></dt>

<dd> Specify overlap for frames. If set to 0 (default) no frame overlapping is done.

Using >0 and <1 values will make less conservative gain adjustments, like

when framelen option is set to smaller value, if framelen option value is

compensated for non-zero overlap then gain adjustments will be smoother across time

compared to zero overlap case.

</dd>

<dt><samp class=”option”>curve, v</samp></dt>

<dd> Specify the peak mapping curve expression which is going to be used when calculating

gain applied to frames. The max output frame gain will still be limited by other

options mentioned previously for this filter.

The expression can contain the following constants:

<dl class=”table”>

<dt><samp class=”option”>ch</samp></dt>

<dd> current channel number

</dd>

<dt><samp class=”option”>sn</samp></dt>

<dd> current sample number

</dd>

<dt><samp class="option">nb_channels</samp></dt>

<dd> number of channels

</dd>

<dt><samp class="option">t</samp></dt>

<dd> timestamp expressed in seconds

</dd>

<dt><samp class="option">sr</samp></dt>

<dd> sample rate

</dd>

<dt><samp class="option">p</samp></dt>

<dd> current frame peak value

</dd>

</dl>

</dd>

</dl>

 <h4 class="subsection">8.85.1 Commands# TOC</h4>

This filter supports the all above options as commands.
  <h3 class="section">8.86 earwax# TOC</h3>

Make audio easier to listen to on headphones. This filter adds ‘cues’ to 44.1kHz stereo (i.e. audio CD format) audio so that when listened to on headphones the stereo image is moved from inside your head (standard for headphones) to outside and in front of the listener (standard for speakers). Ported from SoX. <h3 class="section">8.87 equalizer# TOC</h3>

Apply a two-pole peaking equalisation (EQ) filter. With this filter, the signal-level at and around a selected frequency can be increased or decreased, whilst (unlike bandpass and bandreject filters) that at all other frequencies is unchanged. In order to produce complex equalisation curves, this filter can be given several times, each with a different central frequency. The filter accepts the following options: <dl class="table"> <dt><samp class="option">frequency, f</samp></dt> <dd> Set the filter’s central frequency in Hz. </dd> <dt><samp class="option">width_type, t</samp></dt> <dd> Set method to specify band-width of filter. <dl class="table"> <dt><samp class="option">h</samp></dt> <dd> Hz </dd> <dt><samp class="option">q</samp></dt> <dd> Q-Factor </dd> <dt><samp class="option">o</samp></dt> <dd> octave </dd> <dt><samp class="option">s</samp></dt> <dd> slope </dd> <dt><samp class="option">k</samp></dt> <dd> kHz </dd> </dl>

</pre>

 <h4 class=”subsection”>8.99.2 Commands# TOC</h4>

This filter supports all options that are exported by plugin as commands. <h3 class=”section”>8.100 mcom-

pand# TOC</h3> Multiband Compress or expand the audio’s dynamic range. The input audio is divided into bands using 4th order Linkwitz-Riley IIRs. This is akin to the crossover of a loudspeaker, and results in flat frequency response when absent compander action. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>args</samp></dt> <dd> This option syntax is: attack,decay,[attack,decay..] soft-knee points crossover_frequency [delay [initial_volume [gain]]] | attack,decay ... For explanation of each item refer to compand filter documentation. </dd> </dl>

 <h3 class=”section”>8.101 pan# TOC</h3>

Mix channels with specific gain levels. The filter accepts the output channel layout followed by a set of channels definitions. This filter is also designed to efficiently remap the channels of an audio stream. The filter accepts parameters of the form: "<var class=”var”>l</var>|<var class=”var”>outdef</var>|<var class=”var”>outdef</var>|..." <dl class=”table”> <dt><samp class=”option”>l</samp></dt> <dd> output channel layout or number of channels </dd> <dt><samp class=”option”>outdef</samp></dt> <dd> output channel specification, of the form: "<var class=”var”>out_name</var>=[<var class=”var”>gain</var>*]<var class=”var”>in_name</var>[(+-)[<var class=”var”>gain</var>*]<var class=”var”>in_name</var>...]" </dd> <dt><samp class=”option”>out_name</samp></dt> <dd> output channel to define, either a channel name (FL, FR, etc.) or a channel number (c0, c1, etc.) </dd> <dt><samp class=”option”>gain</samp></dt> <dd> multiplicative coefficient for the channel, 1 leaving the volume unchanged </dd> <dt><samp class=”option”>in_name</samp></dt> <dd> input channel to use, see out_name for details; it is not possible to mix named and numbered input channels </dd> </dl>

If the ‘=’ in a channel specification is replaced by ‘<’, then the gains for that specification will be renormalized so that the total is 1, thus avoiding clipping noise. <h4 class=”subsection”>8.101.1 Mixing examples# TOC</h4>

For example, if you want to down-mix from stereo to mono, but with a bigger factor for the left channel: <pre

class=”example-preformatted”>pan=1c|c0=0.9*c0+0.1*c1 </pre>

A customized down-mix to stereo that works automatically for 3-, 4-, 5- and 7-channels surround: <pre class=”example-preformatted”>pan=stereo| FL < FL + 0.5*FC + 0.6*BL + 0.6*SL | FR < FR + 0.5*FC + 0.6*BR + 0.6*SR </pre>

Note that <code class=”command”>ffmpeg</code> integrates a default down-mix (and up-mix) system that should be preferred (see "-ac" option) unless you have very specific needs. <h4 class=”subsection”>8.101.2 Remapping examples# TOC</h4>

The channel remapping will be effective if, and only if: <ul class=”itemize mark-bullet”> gain coefficients are zeroes or ones, only one input per channel output,

If all these conditions are satisfied, the filter will notify the user ("Pure channel mapping detected"), and use an optimized and lossless method to do the remapping. For example, if you have a 5.1 source and want a stereo audio stream by dropping the extra channels: <pre class=”example-preformatted”>pan="stereo| c0=FL | c1=FR" </pre>

Given the same source, you can also switch front left and front right channels and keep the input channel layout: <pre class=”example-preformatted”>pan="5.1| c0=c1 | c1=c0 | c2=c2 | c3=c3 | c4=c4 | c5=c5" </pre>

If the input is a stereo audio stream, you can mute the front left channel (and still keep the stereo channel layout) with: <pre class=”example-preformatted”>pan="stereo|c1=c1" </pre>

Still with a stereo audio stream input, you can copy the right channel in both front left and right: <pre class=”example-preformatted”>pan="stereo| c0=FR | c1=FR" </pre>

 <h3 class=”section”>8.102 replaygain# TOC</h3>

ReplayGain scanner filter. This filter takes an audio stream as an input and outputs it unchanged. At end of filtering it displays <code class=”code”>track_gain</code> and <code class=”code”>track_peak</code>. The filter accepts the following exported read-only options: <dl class=”table”> <dt><samp class=”option”>track_gain</samp></dt> <dd> Exported track gain in dB at end of stream. </dd>

<dt><samp class="option">track_peak</samp></dt> <dd> Exported track peak at end of stream. </dd> </dl>

 <h4 class="subsection">8.105.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h4 class="subsection">8.105.2 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Full ffmpeg example taking 2 audio inputs, 1st input to be compressed depending on the signal of 2nd input and later compressed signal to be merged with 2nd input: <pre class="example-preformatted">ffmpeg -i main.flac -i sidechain.flac -filter_complex "[1:a]asplit=2[sc][mix];[0:a][sc]sidechaincompress[compr];[compr][mix]amerge" </pre>

 <h3 class="section">8.106 sidechaingate# TOC</h3>

A sidechain gate acts like a normal (wideband) gate but has the ability to filter the detected signal before sending it to the gain reduction stage. Normally a gate uses the full range signal to detect a level above the threshold.

For example: If you cut all lower frequencies from your sidechain signal the gate will decrease the volume of your track only if not enough highs appear. With this technique you are able to reduce the resonation of a natural drum or remove "rumbling" of muted strokes from a heavily distorted guitar. It needs two input streams and returns one output stream. First input stream will be processed depending on second stream signal. The filter accepts the following options: <dl class="table"> <dt><samp class="option">level_in</samp></dt> <dd> Set input level before filtering. Default is 1. Allowed range is from 0.015625 to 64. </dd> <dt><samp class="option">mode</samp></dt> <dd> Set the mode of operation. Can be <code class="code">upward</code> or <code class="code">downward</code>. Default is <code class="code">downward</code>. If set to <code class="code">upward</code> mode, higher parts of signal will be amplified, expanding dynamic range in upward direction. Otherwise, in case of <code class="code">downward</code> lower parts of signal will be reduced. </dd> <dt><samp class="option">range</samp></dt> <dd> Set the level of gain reduction when the signal is below the threshold. Default is 0.06125. Allowed range is from 0 to 1. mands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">8.107 silencedetect# TOC</h3>

Detect silence in an audio stream. This filter logs a message when it detects that the input audio volume is less or equal to a noise tolerance value for a duration greater or equal to the minimum detected noise duration. The printed times and duration are expressed in seconds. The <code class="code">lavfi.silence_start</code> or <code class="code">lavfi.silence_start.X</code> metadata key is set on the first frame whose timestamp equals or exceeds the detection duration and it contains the timestamp of the first frame of the silence. The <code class="code">lavfi.silence_duration</code> or <code class="code">lavfi.silence_duration.X</code> and <code class="code">lavfi.silence_end</code> or <code class="code">lavfi.silence_end.X</code> metadata keys are set on the first frame after the silence. If <samp class="option">mono</samp> is enabled, and each channel is evaluated separately, the <code class="code">.X</code> suffixed keys are used, and <code class="code">X</code> corresponds to the channel number. The filter accepts the following options: <dl class="table"> <dt><samp class="option">noise, n</samp></dt> <dd> Set noise tolerance. Can be specified in dB (in case "dB" is appended to the specified value) or amplitude ratio. Default is -60dB, or 0.001. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Set silence duration until notification (default is 2 seconds). See <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#time-duration-syntax">the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. </dd> <dt><samp class="option">mono, m</samp></dt> <dd> Process each channel separately, instead of combined. By default is disabled. </dd> </dl>

 <h4 class="subsection">8.107.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Detect 5 seconds of silence with -50dB noise tolerance: <pre class="example-preformatted">silencedetect=n=-50dB:d=5 </pre>

Complete example with <code class="command">ffmpeg</code> to detect silence with 0.0001 noise tolerance in <samp class="file">silence.mp3</samp>:

 <pre class=”example-preformatted”>ffmpeg -i silence.mp3 -af silencedetect=noise=0.0001 -f null - </pre>

 <h3 class=”section”>8.108 silenceremove# TOC</h3>

Remove silence from the beginning, middle or end of the audio.

The filter accepts the following options:

<dl class=”table”>

<dt><samp class=”option”>start_periods</samp></dt>

<dd> This value is used to indicate if audio should be trimmed at beginning of

the audio. A value of zero indicates no silence should be trimmed from the

beginning. When specifying a non-zero value, it trims audio up until it

finds non-silence. Normally, when trimming silence from beginning of audio

the <var class=”var”>start_periods</var> will be <code class=”code”>1</code> but it can be increased to higher

values to trim all audio up to specific count of non-silence periods.

Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>start_duration</samp></dt>

<dd> Specify the amount of time that non-silence must be detected before it stops

trimming audio. By increasing the duration, bursts of noises can be treated

as silence and trimmed off. Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>start_threshold</samp></dt>

<dd> This indicates what sample value should be treated as silence. For digital

audio, a value of <code class=”code”>0</code> may be fine but for audio recorded from analog,

you may wish to increase the value to account for background noise.

Can be specified in dB (in case "dB" is appended to the specified value)

or amplitude ratio. Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>start_silence</samp></dt>

<dd> Specify max duration of silence at beginning that will be kept after

trimming. Default is 0, which is equal to trimming all samples detected

as silence.

</dd>

<dt><samp class=”option”>start_mode</samp></dt>

<dd> Specify mode of detection of silence end at start of multi-channel audio.

Can be <var class=”var”>any</var> or <var class=”var”>all</var>. Default is <var class=”var”>any</var>.

With <var class=”var”>any</var>, any sample from any channel that is detected as non-silence

will trigger end of silence trimming at start of audio stream.

With <var class=”var”>all</var>, only if every sample from every channel is detected as non-silence

will trigger end of silence trimming at start of audio stream, limited usage.

</dd>

<dt><samp class=”option”>stop_periods</samp></dt>

<dd> Set the count for trimming silence from the end of audio. When specifying a

positive value, it trims audio after it finds specified silence period.

To remove silence from the middle of a file, specify a <var class=”var”>stop_periods</var>

that is negative. This value is then treated as a positive value and is

used to indicate the effect should restart processing as specified by

<var class=”var”>stop_periods</var>, making it suitable for removing periods of silence

in the middle of the audio.

Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>stop_duration</samp></dt>

<dd> Specify a duration of silence that must exist before audio is not copied any

more. By specifying a higher duration, silence that is wanted can be left in

the audio.

Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>stop_threshold</samp></dt>

<dd> This is the same as <samp class=”option”>start_threshold</samp> but for trimming silence from

the end of audio.

Can be specified in dB (in case "dB" is appended to the specified value)

or amplitude ratio. Default value is <code class=”code”>0</code>.

</dd>

<dt><samp class=”option”>stop_silence</samp></dt>

<dd> Specify max duration of silence at end that will be kept after

trimming. Default is 0, which is equal to trimming all samples detected

as silence.

</dd>

<dt><samp class=”option”>stop_mode</samp></dt>

<dd> Specify mode of detection of silence start after start of multi-channel audio.

Can be <var class="var">any</var> or <var class="var">all</var>. Default is <var class="var">all</var>.

With <var class="var">any</var>, any sample from any channel that is detected as silence

will trigger start of silence trimming after start of audio stream, limited usage.

With <var class="var">all</var>, only if every sample from every channel is detected as silence

will trigger start of silence trimming after start of audio stream.

</dd>

<dt><samp class="option">detection</samp></dt>

<dd> Set how is silence detected.

<dl class="table">

<dt><samp class="option">avg</samp></dt>

<dd> Mean of absolute values of samples in moving window.

</dd>

<dt><samp class="option">rms</samp></dt>

<dd> Root squared mean of absolute values of samples in moving window.

</dd>

<dt><samp class="option">peak</samp></dt>

<dd> Maximum of absolute values of samples in moving window.

<dt><samp class="option">median</samp></dt>

<dd> Median of absolute values of samples in moving window.

</dd>

<dt><samp class="option">ptp</samp></dt>

<dd> Absolute of max peak to min peak difference of samples in moving window.

</dd>

<dt><samp class="option">dev</samp></dt>

<dd> Standard deviation of values of samples in moving window.

</dd>

</dl>

Default value is <code class="code">rms</code>.

</dd>

<dt><samp class="option">window</samp></dt>

<dd> Set duration in number of seconds used to calculate size of window in number

of samples for detecting silence. Using <code class="code">0</code> will effectively disable

any windowing and use only single sample per channel for silence detection.

In that case it may be needed to also set <samp class="option">start_silence</samp> and/or

<samp class="option">stop_silence</samp> to nonzero values with also <samp class="option">start_duration</samp> and/or

<samp class="option">stop_duration</samp> to nonzero values.

Default value is <code class="code">0.02</code>. Allowed range is from <code class="code">0</code> to <code class="code">10</code>.

</dd>

<dt><samp class="option">timestamp</samp></dt>

<dd> Set processing mode of every audio frame output timestamp.

<dl class="table">

<dt><samp class="option">write</samp></dt>

<dd> Full timestamps rewrite, keep only the start time for the first output frame.

</dd>

<dt><samp class="option">copy</samp></dt>

<dd> Non-dropped frames are left with same timestamp as input audio frame.

</dd>

</dl>

Defaults value is <code class=”code”>write</code>.

</dd>

</dl>

 <h4 class=”subsection”>8.108.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> The following example shows how this filter can be used to start a recording that does not contain the delay at the start which usually occurs between pressing the record button and the start of the performance: <pre class=”example-preformatted”>silenceremove=start_periods=1:start_duration=5:start_threshold=0.02
</pre>

Trim all silence encountered from beginning to end where there is more than 1 second of silence in audio: <pre class=”example-preformatted”>silenceremove=stop_periods=-1:stop_duration=1:stop_threshold=-90dB </pre>

Trim all digital silence samples, using peak detection, from beginning to end where there is more than 0 samples of digital silence in audio and digital silence is detected in all channels at same positions in stream: <pre class=”example-preformatted”>silenceremove=window=0:detection=peak:stop_mode=all:start_mode=all:stop_periods=-1:stop_threshold=0 </pre>

Trim every 2nd encountered silence period from beginning to end where there is more than 1 second of silence per silence period in audio: <pre class=”example-preformatted”>silenceremove=stop_periods=-2:stop_duration=1:stop_threshold=-90dB </pre>

Similar as above, but keep maximum of 0.5 seconds of silence from each trimmed period: <pre class=”example-preformatted”>silenceremove=stop_periods=-2:stop_duration=1:stop_threshold=-90dB:stop_silence=0.5 </pre>

Similar as above, but keep maximum of 1.5 seconds of silence from start of audio: <pre class=”example-preformatted”>silenceremove=stop_periods=-2:stop_duration=1:stop_threshold=-90dB:stop_silence=0.5:start_periods=1:start_duration=1:start_silence=1.5:stop_threshold=-90dB </pre>

 <h4 class=”subsection”>8.108.2 Commands# TOC</h4>

This filter supports some above options as commands. <h3 class=”section”>8.109 sofalizer# TOC</h3>

SOFAlizer uses head-related transfer functions (HRTFs) to create virtual loudspeakers around the user for binaural listening via headphones (audio formats up to 9 channels supported). The HRTFs are stored in SOFA files (see http://www.sofacoustics.org/ for a database). SOFAlizer is developed at the Acoustics Research Institute (ARI) of the Austrian Academy of Sciences. To enable compilation of this filter you need to configure FFmpeg with <code class=”code”>--enable-libmysofa</code>. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sofa</samp></dt> <dd> Set the SOFA file used for rendering. </dd> <dt><samp class=”option”>gain</samp></dt> <dd> Set gain applied to audio. Value is in dB. Default is 0. </dd> <dt><samp class=”option”>rotation</samp></dt> <dd> Set rotation of virtual loudspeakers in deg. Default is 0. </dd> <dt><samp class=”option”>elevation</samp></dt> <dd> Set elevation of virtual speakers in deg. Default is 0. </dd> <dt><samp class=”option”>radius</samp></dt> <dd> Set distance in meters between loudspeakers and the listener with near-field HRTFs. Default is 1. </dd> <dt><samp class=”option”>type</samp></dt> <dd> Set processing type. Can be <var class=”var”>time</var> or <var class=”var”>freq</var>. <var class=”var”>time</var> is processing audio in time domain which is slow. <var class=”var”>freq</var> is processing audio in frequency domain which is fast. Default is <var class=”var”>freq</var>. </dd> <dt><samp class=”option”>speakers</samp></dt> <dd> Set custom positions of virtual loudspeakers. Syntax for this option is: <CH> <AZIM> <ELEV>[|<CH> <AZIM> <ELEV>|...]. Each virtual loudspeaker is described with short channel name following with azimuth and elevation in degrees. Each virtual loudspeaker description is separated by ’|’. For example to override front left and front right channel positions use: ’speakers=FL 45 15|FR 345 15’. Descriptions with unrecognised channel names are ignored. </dd> <dt><samp class=”option”>lfegain</samp></dt> <dd> Set custom gain for LFE channels. Value is in dB. Default is 0. </dd> <dt><samp class=”option”>framesize</samp></dt> <dd> Set custom frame size in number of samples. Default is 1024. Allowed range is from 1024 to 96000. Only used if option ‘<samp class=”samp”>type</samp>’ is set to <var class=”var”>freq</var>. </dd> <dt><samp class=”option”>normalize</samp></dt> <dd> Should all IRs be normalized upon importing SOFA file. By default is enabled. </dd> <dt><samp class=”option”>interpolate</samp></dt> <dd> Should

nearest IRs be interpolated with neighbor IRs if exact position does not match. By default is disabled. </dd> <dt><samp class="option">minphase</samp></dt> <dd> Minphase all IRs upon loading of SOFA file. By default is disabled. </dd> <dt><samp class="option">anglestep</samp></dt> <dd> Set neighbor search angle step.  <h3 class="section">8.110 speechnorm# TOC</h3> Speech Normalizer. This filter expands or compresses each half-cycle of audio samples (local set of samples all above or all below zero and between two nearest zero crossings) depending on threshold value, so audio reaches target peak value under conditions controlled by below options. The filter accepts the following options: <dl class="table"> <dt><samp class="option">peak, p</samp></dt> <dd> Set the expansion target peak value. This specifies the highest allowed absolute amplitude level for the normalized audio input. Default value is 0.95. Allowed range is from 0.0 to 1.0. </dd> <dt><samp class="option">expansion, e</samp></dt> <dd> Set the maximum expansion factor. Allowed range is from 1.0 to 50.0. Default value is 2.0. This option controls maximum local half-cycle of samples expansion. The maximum expansion would be such that local peak value reaches target peak value but never to surpass it and that ratio between new and previous peak value does not surpass this option value. </dd> <dt><samp class="option">compression, c</samp></dt> <dd> Set the maximum compression factor. Allowed range is from 1.0 to 50.0. Default

value is 2.0. This option controls maximum local half-cycle of samples compression. This option is used only if <samp class=”option”>threshold</samp> option is set to value greater than 0.0, then in such cases when local peak is lower or same as value set by <samp class=”option”>threshold</samp> all samples belonging to that peak’s half-cycle will be compressed by current compression factor. </dd> <dt><samp class=”option”>threshold, t</samp></dt> <dd> Set the threshold value. Default value is 0.0. Allowed range is from 0.0 to 1.0. This option specifies which half-cycles of samples will be compressed and which will be expanded. Any half-cycle samples with their local peak value below or same as this option value will be compressed by current compression factor, otherwise, if greater than threshold value they will be expanded with expansion factor so that it could reach peak target value but never surpass it. </dd> <dt><samp class=”option”>raise, r</samp></dt> <dd> Set the expansion raising amount per each half-cycle of samples. Default value is 0.001. Allowed range is from 0.0 to 1.0. This controls how fast expansion factor is raised per each new half-cycle until it reaches <samp class=”option”>expansion</samp> value. Setting this options too high may lead to distortions. </dd> <dt><samp class=”option”>fall, f</samp></dt> <dd> Set the compression raising amount per each half-cycle of samples. Default value is 0.001. Allowed range is from 0.0 to 1.0. This controls how fast compression factor is raised per each new half-cycle until it reaches <samp class=”option”>compression</samp> value. </dd> <dt><samp class=”option”>channels, h</samp></dt> <dd> Specify which channels to filter, by default all available channels are filtered. </dd> <dt><samp class=”option”>invert, i</samp></dt> <dd> Enable inverted filtering, by default is disabled. This inverts interpretation of <samp class=”option”>threshold</samp> option. When enabled any half-cycle of samples with their local peak value below or same as <samp class=”option”>threshold</samp> option will be expanded otherwise it will be compressed. </dd> <dt><samp class=”option”>link, l</samp></dt> <dd> Link channels when calculating gain applied to each filtered channel sample, by default is disabled. When disabled each filtered channel gain calculation is independent, otherwise when this option is enabled the minimum of all possible gains for each filtered channel is used. </dd> <dt><samp class=”option”>rms, m</samp></dt> <dd> Set the expansion target RMS value. This specifies the highest allowed RMS level for the normalized audio input. Default value is 0.0, thus disabled. Allowed range is from 0.0 to 1.0. </dd> </dl>

This filter supports the following commands: <dl class=”table”>
<dt><samp class=”option”>volume</samp></dt> <dd> Modify the volume expression. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h4 class=”subsection”>8.120.2 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Halve the input audio volume: <pre class=”example-preformatted”>volume=volume=0.5
volume=volume=1/2 volume=volume=-6.0206dB </pre>

In all the above example the named key for <samp class=”option”>volume</samp> can be omitted, for example like in: <pre class=”example-preformatted”>volume=0.5 </pre>

Increase input audio power by 6 decibels using fixed-point precision:
 <pre class=”example-preformatted”>volume=volume=6dB:precision=fixed
</pre>

Fade volume after time 10 with an annihilation period of 5 seconds:
 <pre class=”example-preformatted”>volume='if(lt(t,10),1,max(1-(t-10)/5,0))':eval=frame </pre>

 <h3 class=”section”>8.121 volumedetect# TOC</h3>

Detect the volume of the input video. The filter has no parameters. It supports only 16-bit signed integer samples, so the input will be converted when needed. Statistics about the volume will be printed in the log when the input stream end is reached. In particular it will show the mean volume (root mean square), maximum volume (on a per-sample basis), and the beginning of a histogram of the registered volume values (from the maximum value to a cumulated 1/1000 of the samples).
All volumes are in decibels relative to the maximum PCM value.
 <h4 class=”subsection”>8.121.1 Examples# TOC</h4>

Here is an excerpt of the output: <pre class=”example-preformatted”>[Parsed_volumedetect_0 0xa23120]

mean_volume: -27 dB [Parsed_volumedetect_0 0xa23120] max_volume: -4 dB [Parsed_volumedetect_0 0xa23120] histogram_4db: 6 [Parsed_volumedetect_0 0xa23120] histogram_5db: 62 [Parsed_volumedetect_0 0xa23120] histogram_6db: 286 [Parsed_volumedetect_0 0xa23120] histogram_7db: 1042 [Parsed_volumedetect_0 0xa23120] histogram_8db: 2551 [Parsed_volumedetect_0 0xa23120] histogram_9db: 4609 [Parsed_volumedetect_0 0xa23120] histogram_10db: 8409 </pre>

It means that: <ul class="itemize mark-bullet"> The mean square energy is approximately -27 dB, or 10^-2.7. The largest sample is at -4 dB, or more precisely between -4 dB and -5 dB. There are 6 samples at -4 dB, 62 at -5 dB, 286 at -6 dB, etc.

In other words, raising the volume by +4 dB does not cause any clipping, raising it by +5 dB causes clipping for 6 samples, etc. <h3 class="section">8.122 whisper# TOC</h3>

It runs automatic speech recognition using the OpenAI’s Whisper model. It requires the whisper.cpp library (https://github.com/ggml-org/whisper.cpp) as a prerequisite. After installing the library it can be enabled using: <code class="code">./configure --enable-whisper</code>. The filter has following options: <dl class="table"> <dt><samp class="option">model</samp></dt> <dd> The file path of the downloaded whisper.cpp model (mandatory). </dd> <dt><samp class="option">language</samp></dt> <dd> The language to use for transcription. Besides a language code, the following special values enable auto-detection: <dl class="table"> <dt>‘<samp class="samp">eval</samp>’</dt> <dd> Re-run language detection on every queued chunk. This costs an extra encoder pass per chunk and the detected language may change mid-file. </dd> <dt>‘<samp class="samp">lock</samp>’</dt> <dd> Detect the language on the first chunk that produces transcribed text, then reuse it for the remaining chunks. </dd> <dt>‘<samp class="samp">auto</samp>’</dt> <dd> Currently an alias for ‘<samp class="samp">eval</samp>’. This may change in a future version, so use ‘<samp class="samp">eval</samp>’ or ‘<samp class="samp">lock</samp>’ if the behavior matters. </dd> </dl>

Default value: <code class="code">"auto"</code> </dd> <dt><samp class="option">translate</samp></dt> <dd> If enabled, translate the transcription from the source language to English. A multilingual model is required to enable this option. Default value: <code class="code">"false"</code> </dd> <dt><samp

class=”option”>queue</samp></dt> <dd> The maximum size that will be queued into the filter before processing the audio with whisper. Using a small value the audio stream will be processed more often, but the transcription quality will be lower and the required processing power will be higher. Using a large value (e.g. 10-20s) will produce more accurate results using less CPU (as using the whisper-cli tool), but the transcription latency will be higher, thus not useful to process real-time streams. Consider using the vad_model option associated with a large queue value. Default value: <code class=”code”>"3"</code> </dd> <dt><samp class=”option”>use_gpu</samp></dt> <dd> If the GPU support should be enabled. Default value: <code class=”code”>"true"</code> </dd> <dt><samp class=”option”>gpu_device</samp></dt> <dd> The GPU device index to use. Default value: <code class=”code”>"0"</code> </dd> <dt><samp class=”option”>destination</samp></dt> <dd> If set, the transcription output will be sent to the specified file or URL (use one of the FFmpeg AVIO protocols); otherwise, the output will be logged as info messages. The output will also be set in the "lavfi.whisper.text" frame metadata. If the destination is a file and it already exists, it will be overwritten. </dd> <dt><samp class=”option”>format</samp></dt> <dd> The destination format string; it could be "text" (only the transcribed text will be sent to the destination), "srt" (subtitle format) or "json". JSON segments include a <code class=”code”>language</code> field containing the language code reported by whisper.cpp for the transcription chunk, or <code class=”code”>unknown</code> if none is available. All segments from the same chunk have the same language. Default value: <code class=”code”>"text"</code> </dd> <dt><samp class=”option”>max_len</samp></dt> <dd> Maximum segment length in characters. When set to a value greater than 0, transcription segments will be split by word to not exceed this length. This is useful for generating subtitles with shorter lines. Default value: <code class=”code”>"0"</code> </dd> <dt><samp class=”option”>vad_model</samp></dt> <dd> Path to the VAD model file. If set, the filter will load an additional voice activity detection module (https://github.com/snakers4/silero-vad) that will be used to fragment the audio queue; use this option setting a valid path obtained from the whisper.cpp repository (e.g. "../whisper.cpp/models/ggml-silero-v5.1.2.bin") and increase the queue parameter to a higher value (e.g. 20). </dd> <dt><samp class=”option”>vad_threshold</samp></dt> <dd> The VAD threshold to use.  <h2 class="chapter">9 Audio Sources# TOC</h2>

Below is a description of the currently available audio sources. <h3 class="section">9.1 abuffer# TOC</h3>

Buffer audio frames, and make them available to the filter chain. This source is mainly intended for a programmatic use, in particular through the interface defined in <samp class="file">libavfilter/buffersrc.h</samp>. It accepts the following parameters: <dl class="table"> <dt><samp class="option">time_base</samp></dt> <dd> The timebase which will be used for timestamps of submitted frames. It must be either a floating-point number or in <var class="var">numerator</var>/<var class="var">denominator</var> form. </dd> <dt><samp class="option">sample_rate</samp></dt> <dd> The sample rate of the incoming audio buffers. </dd> <dt><samp class="option">sample_fmt</samp></dt> <dd> The sample format of the incoming audio buffers. Either a sample format name or its corresponding integer representation from the enum AVSample-

Format in <samp class="file">libavutil/samplefmt.h</samp> </dd> <dt><samp class="option">channel_layout</samp></dt> <dd> The channel layout of the incoming audio buffers. Either a channel layout name from channel_layout_map in <samp class="file">libavutil/channel_layout.c</samp> or its corresponding integer representation from the AV_CH_LAYOUT_* macros in <samp class="file">libavutil/channel_layout.h</samp> </dd> <dt><samp class="option">channels</samp></dt> <dd> The number of channels of the incoming audio buffers. If both <var class="var">channels</var> and <var class="var">channel_layout</var> are specified, then they must be consistent. </dd> </dl>

 <h4 class="subsection">9.1.1 Examples# TOC</h4>

 <pre class="example-preformatted">abuffer=sample_rate=44100:sample_fmt=s16p
</pre>

will instruct the source to accept planar 16bit signed stereo at 44100Hz. Since the sample format with name "s16p" corresponds to the number 6 and the "stereo" channel layout corresponds to the value 0x3, this is equivalent to: <pre class="example-preformatted">abuffer=sample_rate=44100:sample_fmt=6:channel_layout=0x3
</pre>

 <h3 class="section">9.2 aevalsrc# TOC</h3>

Generate an audio signal specified by an expression. This source accepts in input one or more expressions (one for each channel), which are evaluated and used to generate a corresponding audio signal. This source accepts the following options: <dl class="table"> <dt><samp class="option">exprs</samp></dt> <dd> Set the ’|’-separated expressions list for each separate channel. In case the <samp class="option">channel_layout</samp> option is not specified, the selected channel layout depends on the number of provided expressions. Otherwise the last specified expression is applied to the remaining output channels. </dd> <dt><samp class="option">channel_layout, c</samp></dt> <dd> Set the channel layout. The number of channels in the specified layout must be equal to the number of specified expressions. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Set the minimum duration of the sourced audio. See <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#time-duration-syntax">the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. Note that the resulting duration may be greater than the specified duration, as the generated

audio is always cut at the end of a complete frame. If not specified, or the expressed duration is negative, the audio is supposed to be generated forever. </dd> <dt><samp class="option">nb_samples, n</samp></dt> <dd> Set the number of samples per channel per each output frame, default to 1024. </dd> <dt><samp class="option">sample_rate, s</samp></dt> <dd> Specify the sample rate, default to 44100. </dd> </dl>

Each expression in <var class="var">exprs</var> can contain the following constants: <dl class="table"> <dt><samp class="option">n</samp></dt> <dd> number of the evaluated sample, starting from 0 </dd> <dt><samp class="option">t</samp></dt> <dd> time of the evaluated sample expressed in seconds, starting from 0 </dd> <dt><samp class="option">s</samp></dt> <dd> sample rate </dd> </dl>

 <h4 class="subsection">9.2.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Generate silence: <pre class="example-preformatted">aevalsrc=0 </pre>

Generate a sin signal with frequency of 440 Hz, set sample rate to 8000 Hz: <pre class="example-preformatted">aevalsrc="sin(440*2*PI*t):s=8000" </pre>

Generate a two channels signal, specify the channel layout (Front Center + Back Center) explicitly: <pre class="example-preformatted">aevalsrc="sin(420*2*PI*t)|cos(430*2*PI*t):c=FC|BC" </pre>

Generate white noise: <pre class="example-preformatted">aevalsrc="-2+random(0)" </pre>

Generate an amplitude modulated signal: <pre class="example-preformatted">aevalsrc="sin(10*2*PI*t)*sin(880*2*PI*t)" </pre>

Generate 2.5 Hz binaural beats on a 360 Hz carrier: <pre class="example-preformatted">aevalsrc="0.1*sin(2*PI*(360-2.5/2)*t) | 0.1*sin(2*PI*(360+2.5/2)*t)" </pre>

 <h3 class="section">9.3 afdelaysrc# TOC</h3>

Generate a fractional delay FIR coefficients. The resulting stream can be used with afir filter for filtering the audio signal. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>delay, d</samp></dt> <dd> Set the fractional delay. Default is 0. </dd> <dt><samp class=”option”>sample_rate, r</samp></dt> <dd> Set the sample rate, default is 44100. </dd> <dt><samp class=”option”>nb_samples, n</samp></dt> <dd> Set the number of samples per each frame. Can be <code class="code">linear</code> or <code class="code">min</code>: minimum-phase. Default is minimum-phase filter. </dd> </dl>

 <h3 class="section">9.5 afirsrc# TOC</h3>

Generate a FIR coefficients using frequency sampling method. The resulting stream can be used with afir filter for filtering the audio signal. The filter accepts the following options: <dl class="table"> <dt><samp class="option">taps, t</samp></dt> <dd> Set number of filter coefficients in output audio stream. Default value is 1025. </dd> <dt><samp class="option">frequency, f</samp></dt> <dd> Set frequency points from where magnitude and phase are set. This must be in non decreasing order, and first element must be 0, while last element must be 1. Elements are separated by white spaces. </dd> <dt><samp class="option">magnitude, m</samp></dt> <dd> Set magnitude value for every frequency point set by <samp class="option">frequency</samp>. Number of values must be same as number of frequency points. Values are separated by white spaces. </dd> <dt><samp class="option">phase, p</samp></dt> <dd> Set phase value for every frequency point set by <samp class="option">frequency</samp>. Number of values must be same as number of frequency points. Values are separated by white spaces. </dd> <dt><samp class="option">sample_rate, r</samp></dt> <dd> Set sample rate, default is 44100. </dd> <dt><samp class="option">nb_samples, n</samp></dt> <dd> Set number of samples per each frame. Default is 1024. </dd> <dt><samp

class=”option”>win_func, w</samp></dt> <dd> Set window function. Default is blackman. </dd> </dl>

 <h3 class=”section”>9.6 anullsrc# TOC</h3>

The null audio source, return unprocessed audio frames. It is mainly useful as a template and to be employed in analysis / debugging tools, or as the source for filters which ignore the input data (for example the sox synth filter). This source accepts the following options: <dl class=”table”> <dt><samp class=”option”>channel_layout, cl</samp></dt> <dd> Specifies the channel layout, and can be either an integer or a string representing a channel layout. The default value of <var class=”var”>channel_layout</var> is "stereo". Check the channel_layout_map definition in <samp class=”file”>libavutil/channel_layout.c</samp> for the mapping between strings and channel layout values. </dd> <dt><samp class=”option”>sample_rate, r</samp></dt> <dd> Specifies the sample rate, and defaults to 44100. </dd> <dt><samp class=”option”>nb_samples, n</samp></dt> <dd> Set the number of samples per requested frames. </dd> <dt><samp class=”option”>duration, d</samp></dt> <dd> Set the duration of the sourced audio. See <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#time-duration-syntax”>the Time duration section in the ffmpeg-utils(1) manual for the accepted syntax. If not specified, or the expressed duration is negative, the audio is supposed to be generated forever. </dd> </dl>

 <h4 class=”subsection”>9.6.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Set the sample rate to 48000 Hz and the channel layout to AV_CH_LAYOUT_MONO. <pre class=”example-preformatted”>anullsrc=r=48000:cl=4 </pre>

Do the same operation with a more obvious syntax: <pre class=”example-preformatted”>anullsrc=r=48000:cl=mono </pre>

All the parameters need to be explicitly defined. <h3 class=”section”>9.7 flite# TOC</h3>

Synthesize a voice utterance using the libflite library. To enable compilation of this filter you need to configure FFmpeg with <code

class=”code”>--enable-libflite</code>. Note that versions of the flite library prior to 2.0 are not thread-safe. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>list_voices</samp></dt> <dd> If set to 1, list the names of the available voices and exit immediately. Default value is 0. </dd> <dt><samp class=”option”>nb_samples, n</samp></dt> <dd> Set the maximum number of samples per frame. Default value is 512. </dd> <dt><samp class=”option”>textfile</samp></dt> <dd> Set the filename containing the text to speak. </dd> <dt><samp class=”option”>text</samp></dt> <dd> Set the text to speak. </dd> <dt><samp class=”option”>voice, v</samp></dt> <dd> Set the voice to use for the speech synthesis. Default value is <code class=”code”>kal</code>. See also the <var class=”var”>list_voices</var> option. </dd> </dl>

 <h4 class=”subsection”>9.7.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Read from file <samp class=”file”>speech.txt</samp>, and synthesize the text using the standard flite voice: <pre class=”example-preformatted”>flite=textfile=speech.txt </pre>

Read the specified text selecting the <code class=”code”>slt</code> voice: <pre class=”example-preformatted”>flite=text='So fare thee well, poor devil of a Sub-Sub, whose commentator I am':voice=slt </pre>

Input text to ffmpeg: <pre class=”example-preformatted”>ffmpeg -f lavfi -i flite=text='So fare thee well, poor devil of a Sub-Sub, whose commentator I am':voice=slt </pre>

Make <samp class=”file”>ffplay</samp> speak the specified text, using <code class=”code”>flite</code> and the <code class=”code”>lavfi</code> device: <pre class=”example-preformatted”>ffplay -f lavfi flite=text='No more be grieved for which that thou hast done.' </pre>

For more information about libflite, check: <a class=”url” href=”http://www.festvox.org/flite/”>http://w
  <h3 class=”section”>9.8 anoisesrc# TOC</h3>

Generate a noise audio signal. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sample_rate, r</samp></dt> <dd> Specify the sample rate. Default value is 48000 Hz. </dd> <dt><samp class=”option”>amplitude, a</samp></dt>

<dd> Specify the amplitude (0.0 - 1.0) of the generated audio stream. Default value is 1.0. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Specify the duration of the generated audio stream. Not specifying this option results in noise with an infinite length. </dd> <dt><samp class="option">color, colour, c</samp></dt> <dd> Specify the color of noise. Available noise colors are white, pink, brown, blue, violet and velvet. Default color is white. </dd> <dt><samp class="option">seed, s</samp></dt> <dd> Specify a value used to seed the PRNG. </dd> <dt><samp class="option">nb_samples, n</samp></dt> <dd> Set the number of samples per each output frame, default is 1024. </dd> <dt><samp class="option">density</samp></dt> <dd> Set the density (0.0 - 1.0) for the velvet noise generator, default is 0.05. </dd> </dl>

 <h4 class="subsection">9.8.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Generate 60 seconds of pink noise, with a 44.1 kHz sampling rate and an amplitude of 0.5: <pre class="example-preformatted">anoisesrc=d=60:c=pink:r=44100:a=0.5 </pre>

 <h3 class="section">9.9 hilbert# TOC</h3>

Generate odd-tap Hilbert transform FIR coefficients. The resulting stream can be used with afir filter for phase-shifting the signal by 90 degrees. This is used in many matrix coding schemes and for analytic signal generation. The process is often written as a multiplication by i (or j), the imaginary unit. The filter accepts the following options: <dl class="table"> <dt><samp class="option">sample_rate, s</samp></dt> <dd> Set sample rate, default is 44100. </dd> <dt><samp class="option">taps, t</samp></dt> <dd> Set length of FIR filter, default is 22051. </dd> <dt><samp class="option">nb_samples, n</samp></dt> <dd> Set number of samples per each frame. </dd> <dt><samp class="option">win_func, w</samp></dt> <dd> Set window function to be used when generating FIR coefficients. </dd> </dl>

 <h3 class="section">9.10 sinc# TOC</h3>

Generate a sinc kaiser-windowed low-pass, high-pass, band-pass, or band-reject FIR coefficients. The resulting stream can be used with afir filter for filtering the audio

signal. The filter accepts the following options: <dl class="table"> <dt><samp class="option">sample_rate, r</samp></dt> <dd> Set sample rate, default is 44100. </dd> <dt><samp class="option">nb_samples, n</samp></dt> <dd> Set number of samples per each frame. Default is 1024. </dd> <dt><samp class="option">hp</samp></dt> <dd> Set high-pass frequency. Default is 0. </dd> <dt><samp class="option">lp</samp></dt> <dd> Set low-pass frequency. Default is 0. If high-pass frequency is lower than low-pass frequency and low-pass frequency is higher than 0 then filter will create band-pass filter coefficients, otherwise band-reject filter coefficients. </dd> <dt><samp class="option">phase</samp></dt> <dd> Set filter phase response. Default is 50. Allowed range is from 0 to 100. </dd> <dt><samp class="option">beta</samp></dt> <dd> Set Kaiser window beta. </dd> <dt><samp class="option">att</samp></dt> <dd> Set stop-band attenuation. Default is 120dB, allowed range is from 40 to 180 dB. </dd> <dt><samp class="option">round</samp></dt> <dd> Enable rounding, by default is disabled. </dd> <dt><samp class="option">hptaps</samp></dt> <dd> Set number of taps for high-pass filter. </dd> <dt><samp class="option">lptaps</samp></dt> <dd> Set number of taps for low-pass filter. </dd> </dl>

 <h3 class="section">9.11 sine# TOC</h3>

Generate an audio signal made of a sine wave with amplitude 1/8. The audio signal is bit-exact. The filter accepts the following options: <dl class="table"> <dt><samp class="option">frequency, f</samp></dt> <dd> Set the carrier frequency. Default is 440 Hz. </dd> <dt><samp class="option">beep_factor, b</samp></dt> <dd> Enable a periodic beep every second with frequency <var class="var">beep_factor</var> times the carrier frequency. Default is 0, meaning the beep is disabled. </dd> <dt><samp class="option">sample_rate, r</samp></dt> <dd> Specify the sample rate, default is 44100. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Specify the duration of the generated audio stream. </dd> <dt><samp class="option">samples_per_frame</samp></dt> <dd> Set the number of samples per output frame. The expression can contain the following constants: <dl class="table"> <dt><samp class="option">n</samp></dt> <dd> The (sequential) number of the output audio frame, starting from 0. </dd> <dt><samp class="option">pts</samp></dt> <dd> The PTS (Presentation TimeStamp) of the output audio frame, expressed in <var class="var">TB</var> units. </dd> <dt><samp class="option">t</samp></dt> <dd> The PTS of the output audio frame, expressed in seconds. </dd> <dt><samp class="option">TB</samp></dt> <dd> The timebase of the output audio frames. </dd> </dl>

Default is <code class="code">1024</code>. </dd> </dl>

 <h2 class="chapter">10 Audio Sinks# TOC</h2>

Below is a description of the currently available audio sinks. <h3 class="section">10.1 abuffersink# TOC</h3>

Buffer audio frames, and make them available to the end of filter chain. This sink is mainly intended for programmatic use, in particular through the interface defined in <samp class="file">libavfilter/buffersink.h</samp> or the options system. It accepts a pointer to an AVABufferSinkContext structure, which defines the incoming buffers’ formats, to be passed as the opaque parameter to <code class="code">avfilter_init_filter</code> for initialization. <h3 class="section">10.2 anullsink# TOC</h3>

Null audio sink; do absolutely nothing with the input audio. It is mainly useful as a template and for use in analysis / debugging tools.

 <h2 class="chapter">11 Video Filters# TOC</h2>

When you configure your FFmpeg build, you can disable any of the existing filters using <code class="code">--disable-filters</code>. The configure output will show the video filters included in your build. Below is a description of the currently available video filters. <h3 class="section">11.1 addroi# TOC</h3>

Mark a region of interest in a video frame. The frame data is passed through unchanged, but metadata is attached to the frame indicating regions of interest which can affect the behaviour of later encoding. Multiple regions can be marked by applying the filter multiple times. <dl class="table"> <dt><samp class="option">x</samp></dt> <dd> Region distance in pixels from the left edge of the frame. </dd> <dt><samp class="option">y</samp></dt> <dd> Region distance in pixels from the top edge of the frame. </dd> <dt><samp class="option">w</samp></dt> <dd> Region width in pixels. </dd> <dt><samp class="option">h</samp></dt> <dd> Region height in pixels. The parameters <var class="var">x</var>, <var class="var">y</var>, <var class="var">w</var> and <var class="var">h</var> are expressions, and may contain the following variables: <dl class="table"> <dt><samp class="option">iw</samp></dt> <dd> Width of the input frame. </dd> <dt><samp class="option">ih</samp></dt> <dd> Height of the input frame. </dd> </dl>

</dd> <dt><samp class="option">qoffset</samp></dt> <dd> Quantisation offset to apply within the region. This must be a real value in the range -1 to +1. A value of zero indicates no quality change. A negative value asks for better quality (less quantisation), while a positive value asks for worse quality (greater quantisation). The range is calibrated so that the extreme values indicate the largest possible offset - if the rest of the frame is encoded with the worst possible quality, an offset of -1 indicates that this region should be encoded with the best possible quality anyway. Intermediate values are then interpolated in some codec-dependent way. For example, in 10-bit H.264 the quantisation parameter varies between -12 and 51. A typical qoffset value of -1/10 therefore indicates that this region should be encoded with a QP around one-tenth of the full range better than the rest of the frame. So, if most of the frame were to be encoded with a QP of around 30, this region would get a QP of around 24 (an offset of approximately -1/10 * (51 - -12) = -6.3). An extreme value of -1 would indicate that this region should be encoded with the best possible quality regardless of the treatment of the rest of the frame - that is, should be encoded at a QP of -12. </dd> <dt><samp class="option">clear</samp></dt> <dd> If set to true, remove any existing regions of interest marked on the frame before adding the new one. </dd> </dl>

 <h4 class="subsection">11.1.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Mark the centre quarter of the frame as interesting. <pre class="example-preformatted">addroi=iw/4:ih/4:iw/2:ih/2:-1/10 </pre> Mark the 100-pixel-wide region on the left edge of the frame as very uninteresting (to be encoded at much lower quality than the rest of the frame). <pre class="example-preformatted">addroi=0:0:100:ih:+1/5 </pre>

 <h3 class="section">11.2 alphaextract# TOC</h3>

Extract the alpha component from the input as a grayscale video. This is especially useful with the <var class="var">alphamerge</var> filter. <h3 class="section">11.3 alphamerge# TOC</h3>

Add or replace the alpha component of the primary input with the grayscale value of a second input. This is intended for use with <var class="var">alphaextract</var> to allow the transmission or storage of frame sequences that have alpha in a format that doesn’t support an alpha channel. For example, to reconstruct full frames from a normal YUV-encoded video and a separate video created with <var class="var">alphaextract</var>, you might use: <pre class="example-preformatted">movie=in_alpha.mkv [alpha]; [in][alpha] alphamerge [out] </pre>

 <h3 class="section">11.4 amplify# TOC</h3>

Amplify differences between current pixel and pixels of adjacent frames in same pixel location. This filter accepts the following options: <dl class="table"> <dt><samp class="option">radius</samp></dt> <dd> Set frame radius. Default is 2. Allowed range is from 1 to 63. For example radius of 3 will instruct filter to calculate average of 7 frames. </dd> <dt><samp class="option">factor</samp></dt> <dd> Set factor to amplify difference. Default is 2. Allowed range is from 0 to 65535. </dd> <dt><samp class="option">threshold</samp></dt> <dd> Set threshold for difference amplification. Any difference greater or equal to this

value will not alter source pixel. Default is 10. Allowed range is from 0 to 65535. </dd> <dt><samp class="option">tolerance</samp></dt> <dd> Set tolerance for difference amplification. Any difference lower to this value will not alter source pixel. Default is 0. Allowed range is from 0 to 65535. </dd> <dt><samp class="option">low</samp></dt> <dd> Set lower limit for changing source pixel. Default is 65535. Allowed range is from 0 to 65535. This option controls maximum possible value that will decrease source pixel value. </dd> <dt><samp class="option">high</samp></dt> <dd> Set high limit for changing source pixel. Default is 65535. Allowed range is from 0 to 65535. This option controls maximum possible value that will increase source pixel value. </dd> <dt><samp class="option">planes</samp></dt> <dd> Set which planes to filter. Valid range is 0 to 5. </dd> <dt><samp class="option">3a</samp></dt> <dd> Set threshold A for 4th plane. Default is 0.02. Valid range is 0 to 0.3. </dd> <dt><samp class="option">3b</samp></dt> <dd> Set threshold B for 4th plane. Default is 0.04. Valid range is 0 to 5. Threshold A is designed to react on abrupt changes in the input signal and threshold B is designed to react on continuous changes in the input signal. </dd> <dt><samp class="option">s</samp></dt> <dd> Set number of frames filter will use for averaging. Default is 9. Must be odd number in range [5, 129]. </dd> <dt><samp class="option">p</samp></dt> <dd> Set what planes of frame filter will use for averaging. Default is all. </dd> <dt><samp class="option">a</samp></dt> <dd> Set what variant of algorithm filter will use for averaging. Default is <code class="code">p</code> parallel. Alternatively can be set to <code class="code">s</code> serial. Parallel can be faster then serial, while other way around is never true. Parallel will abort

early on first change being greater then thresholds, while serial will continue processing other side of frames if they are equal or below thresholds. </dd> <dt><samp class=”option”>0s</samp></dt> <dt><samp class=”option”>1s</samp></dt> <dt><samp class=”option”>2s</samp></dt> <dt><samp class=”option”>3s</samp></dt> <dd> Set sigma for 1st plane, 2nd plane, 3rd plane or 4th plane. Default is 32767. Valid range is from 0 to 32767. This options controls weight for each pixel in radius defined by size. Default value means every pixel have same weight. Setting this option to 0 effectively disables filtering. </dd> </dl>

 <h4 class=”subsection”>11.6.1 Commands# TOC</h4> This filter supports same commands as options except option <code class=”code”>s</code>. The command accepts the same syntax of the corresponding option. <h3 class=”section”>11.7 avgblur# TOC</h3>

Apply average blur filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sizeX</samp></dt> <dd> Set horizontal radius size. </dd> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes to filter. By default all planes are filtered. </dd> <dt><samp class=”option”>sizeY</samp></dt> <dd> Set vertical radius size, if zero it will be same as <code class=”code”>sizeX</code>. Default is <code class=”code”>0</code>. </dd> </dl>

 <h4 class=”subsection”>11.7.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class=”section”>11.8 backgroundkey# TOC</h3>

Turns a static background into transparency. The filter accepts the following option: <dl class=”table”> <dt><samp class=”option”>threshold</samp></dt> <dd> Threshold for scene change detection. </dd> <dt><samp class=”option”>similarity</samp></dt> <dd> Similarity percentage with the background. </dd> <dt><samp class=”option”>blend</samp></dt> <dd> Set the blend amount for pixels that are not similar. </dd> </dl>

 <h4 class="subsection">11.8.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">11.9 bbox# TOC</h3>

Compute the bounding box for the non-black pixels in the input frame luma plane. This filter computes the bounding box containing all the pixels with a luma value greater than the minimum allowed value. The parameters describing the bounding box are printed on the filter log. The filter accepts the following option: <dl class="table"> <dt><samp class="option">min_val</samp></dt> <dd> Set the minimal luma value. Default is <code class="code">16</code>. </dd> </dl>

 <h4 class="subsection">11.9.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">11.10 bilateral# TOC</h3> Apply bilateral filter, spatial smoothing while preserving edges. The filter accepts the following options: <dl class="table"> <dt><samp class="option">sigmaS</samp></dt> <dd> Set sigma of gaussian function to calculate spatial weight. Allowed range is 0 to 512. Default is 0.1. </dd> <dt><samp class="option">sigmaR</samp></dt> <dd> Set sigma of gaussian function to calculate range weight. Allowed range is 0 to 1. Default is 0.1. </dd> <dt><samp class="option">planes</samp></dt> <dd> Set planes to filter. Default is first only. </dd> </dl>

 <h4 class="subsection">11.10.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">11.11 bitplanenoise# TOC</h3>

Show and measure bit plane noise. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>bitplane</samp></dt> <dd> Set which plane to analyze. Default is <code class=”code”>1</code>. </dd> <dt><samp class=”option”>filter</samp></dt> <dd> Filter out noisy pixels from <code class=”code”>bitplane</code> set above. Default is disabled. </dd> </dl>

 <h3 class=”section”>11.12 blackdetect, blackdetect_vulkan# TOC</h3>

Detect video intervals that are (almost) completely black. Can be useful to detect chapter transitions, commercials, or invalid recordings. The filter outputs its detection analysis to both the log as well as frame metadata. If a black segment of at least the specified minimum duration is found, a line with the start and end timestamps as well as duration is printed to the log with level <code class=”code”>info</code>. In addition, a log line with level <code class=”code”>debug</code> is printed per frame showing the black amount detected for that frame. The filter also attaches metadata to the first frame of a black segment with key <code class=”code”>lavfi.black_start</code> and to the first frame after the black segment ends with key <code class=”code”>lavfi.black_end</code>. The value is the frame’s timestamp. This metadata is added regardless of the minimum duration specified. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>black_min_duration, d</samp></dt> <dd> Set the minimum detected black duration expressed in seconds. It must be a non-negative floating point number. Default value is 2.0. </dd> <dt><samp class=”option”>picture_black_ratio_th, pic_th</samp></dt> <dd> Set the threshold for considering a picture "black". Express the minimum value for the ratio: <pre class=”example-preformatted”><var class=”var”>nb_black_pixels</var> / <var class=”var”>nb_pixels</var> </pre>

for which a picture is considered black. Default value is 0.98. </dd> <dt><samp class=”option”>pixel_black_th, pix_th</samp></dt> <dd> Set the threshold for considering a pixel "black". The threshold expresses the maximum pixel luma value for which a pixel is considered "black". The provided value is scaled according to the following equation: <pre class=”example-preformatted”><var class=”var”>absolute_threshold</var> = <var class=”var”>luma_minimum_value</var> + <var class=”var”>pixel_black_th</var> * <var class=”var”>luma_range_size</var> </pre>

<var class=”var”>luma_range_size</var> and <var class=”var”>luma_minimum_value</var> depend on the input video format, the range is [0-255] for YUV full-range

formats and [16-235] for YUV non full-range formats. Default value is 0.10. </dd> <dt><samp class="option">alpha</samp></dt> <dd> If true, check the alpha channel instead of the luma channel. Detects frames which are (almost) transparent, instead of frames which are almost black. Default value is disabled. </dd> </dl>

The following example sets the maximum pixel threshold to the minimum value, and detects only black intervals of 2 or more seconds: <pre class="example-preformatted">blackdetect=d=2:pix_th=0.00 </pre>

 <h3 class="section">11.13 blackframe# TOC</h3>

Detect frames that are (almost) completely black. Can be useful to detect chapter transitions or commercials. Output lines consist of the frame number of the detected frame, the percentage of blackness, the position in the file if known or -1 and the timestamp in seconds. In order to display the output lines, you need to set the loglevel at least to the AV_LOG_INFO value. This filter exports frame metadata <code class="code">lavfi.blackframe.pblack</code>. The value represents the percentage of pixels in the picture that are below the threshold value. It accepts the following parameters: <dl class="table"> <dt><samp class="option">amount</samp></dt> <dd> The percentage of the pixels that have to be below the threshold; it defaults to <code class="code">98</code>. </dd> <dt><samp class="option">threshold, thresh</samp></dt> <dd> The threshold below which a pixel value is considered black; it defaults to <code class="code">32</code>. </dd> </dl>

 <h3 class="section">11.14 blend# TOC</h3>

Blend two video frames into each other. The <code class="code">blend</code> filter takes two input streams and outputs one stream, the first input is the "top" layer and second input is "bottom" layer. By default, the output terminates when the longest input terminates. The <code class="code">tblend</code> (time blend) filter takes two consecutive frames from one single stream, and outputs the result obtained by blending the new frame on top of the old frame. A description of the accepted options follows. <dl class="table"> <dt><samp class="option">c0_mode</samp></dt> <dt><samp class="option">c1_mode</samp></dt> <dt><samp class="option">c2_mode</samp></dt> <dt><samp class="option">c3_mode</samp></dt>

<dt><samp class="option">all_mode</samp></dt> <dd> Set blend mode for specific pixel component or all pixel components in case of <var class="var">all_mode</var>. Default value is <code class="code">normal</code>. Available values for component modes are: <dl class="table"> <dt>‘<samp class="samp">addition</samp>’</dt> <dt>‘<samp class="samp">and</samp>’</dt> <dt>‘<samp class="samp">average</samp>’</dt> <dt>‘<samp class="samp">bleach</samp>’</dt> <dt>‘<samp class="samp">burn</samp>’</dt> <dt>‘<samp class="samp">darken</samp>’</dt> <dt>‘<samp class="samp">difference</samp>’</dt> <dt>‘<samp class="samp">divide</samp>’</dt> <dt>‘<samp class="samp">dodge</samp>’</dt> <dt>‘<samp class="samp">exclusion</samp>’</dt> <dt>‘<samp class="samp">extremity</samp>’</dt> <dt>‘<samp class="samp">freeze</samp>’</dt> <dt>‘<samp class="samp">geometric</samp>’</dt> <dt>‘<samp class="samp">glow</samp>’</dt> <dt>‘<samp class="samp">grainextract</samp>’</dt> <dt>‘<samp class="samp">grainmerge</samp>’</dt> <dt>‘<samp class="samp">hardlight</samp>’</dt> <dt>‘<samp class="samp">hardmix</samp>’</dt> <dt>‘<samp class="samp">hardoverlay</samp>’</dt> <dt>‘<samp class="samp">harmonic</samp>’</dt> <dt>‘<samp class="samp">heat</samp>’</dt> <dt>‘<samp class="samp">interpolate</samp>’</dt> <dt>‘<samp class="samp">lighten</samp>’</dt> <dt>‘<samp class="samp">linearlight</samp>’</dt> <dt>‘<samp class="samp">multiply</samp>’</dt> <dt>‘<samp class="samp">multiply128</samp>’</dt> <dt>‘<samp class="samp">negation</samp>’</dt> <dt>‘<samp class="samp">normal</samp>’</dt> <dt>‘<samp class="samp">or</samp>’</dt> <dt>‘<samp class="samp">overlay</samp>’</dt> <dt>‘<samp class="samp">phoenix</samp>’</dt> <dt>‘<samp class="samp">pinlight</samp>’</dt> <dt>‘<samp class="samp">reflect</samp>’</dt> <dt>‘<samp class="samp">screen</samp>’</dt> <dt>‘<samp class="samp">softdifference</samp>’</dt> <dt>‘<samp class="samp">softlight</samp>’</dt> <dt>‘<samp class="samp">stain</samp>’</dt> <dt>‘<samp class="samp">subtract</samp>’</dt> <dt>‘<samp class="samp">vividlight</samp>’</dt> <dt>‘<samp class="samp">xor</samp>’</dt> </dl>

</dd> <dt><samp class="option">c0_opacity</samp></dt> <dt><samp class="option">c1_opacity</samp></dt> <dt><samp class="option">c2_opacity</samp></dt> <dt><samp class="option">c3_opacity</samp></dt> <dt><samp class="option">all_opacity</samp></dt> <dd> Set blend opacity for specific pixel component or all pixel components in case of <var class="var">all_opacity</var>.  <h3 class="section">11.42 convolve# TOC</h3>

Apply 2D convolution of video stream in frequency domain using second stream as impulse. The filter accepts the following options:

<dl class="table"> <dt><samp class="option">planes</samp></dt> <dd> Set which planes to process. </dd> <dt><samp class="option">impulse</samp></dt> <dd> Set which impulse video frames will be processed, can be <var class="var">first</var> or <var class="var">all</var>. Default is <var class="var">all</var>. </dd> </dl>

The <code class="code">convolve</code> filter also supports the framesync options. <h3 class="section">11.43 copy# TOC</h3>

Copy the input video source unchanged to the output. This is mainly useful for testing purposes. <h3 class="section">11.44 coreimage# TOC</h3> Video filtering on GPU using Apple’s CoreImage API on OSX. Hardware acceleration is based on an OpenGL context. Usually, this means it is processed by video hardware. However, software-based OpenGL implementations exist which means there is no guarantee for hardware processing. It depends on the respective OSX. There are many filters and image generators provided by Apple that come with a large variety of options. The filter has to be referenced by its name along with its options. The coreimage filter accepts the following options: <dl class="table"> <dt><samp class="option">list_filters</samp></dt> <dd> List all available filters and generators along with all their respective options as well as possible minimum and maximum values along with the default values. <pre class="example-preformatted">list_filters=true </pre>

</dd> <dt><samp class="option">filter</samp></dt> <dd> Specify all filters by their respective name and options. Use <var class="var">list_filters</var> to determine all valid filter names and options. Numerical options are specified by a float value and are automatically clamped to their respective value range. Vector and color options have to be specified by a list of space separated float values. Character escaping has to be done. A special option name <code class="code">default</code> is available to use default options for a filter. It is required to specify either <code class="code">default</code> or at least one of the filter options. All omitted options are used with their default values. The syntax of the filter string is as follows: <pre class="example-preformatted">filter=<NAME>@<OPTION>=<VALUE>[@<OPTION>=<VALUE&
</pre>

</dd> <dt><samp class="option">output_rect</samp></dt> <dd> Specify

a rectangle where the output of the filter chain is copied into the input image. It is given by a list of space separated float values: <pre class="example-preformatted">output_rect=x\ y\ width\ height </pre> If not given, the output rectangle equals the dimensions of the input image. The output rectangle is automatically cropped at the borders of the input image. Negative values are valid for each component. <pre class="example-preformatted">output_rect=25\ 25\ 100\ 100 </pre> </dd> </dl>

Several filters can be chained for successive processing without GPU-HOST transfers allowing for fast processing of complex filter chains. Currently, only filters with zero (generators) or exactly one (filters) input image and one output image are supported. Also, transition filters are not yet usable as intended. Some filters generate output images with additional padding depending on the respective filter kernel. The padding is automatically removed to ensure the filter output has the same size as the input image. For image generators, the size of the output image is determined by the previous output image of the filter chain or the input image of the whole filterchain, respectively. The generators do not use the pixel information of this image to generate their output. However, the generated output is blended onto this image, resulting in partial or complete coverage of the output image. The coreimagesrc video source can be used for generating input images which are directly fed into the filter chain. By using it, providing input images by another video source or an input video is not required. <h4 class="subsection">11.44.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> List all filters available: <pre class="example-preformatted">coreimage=list_filters=true </pre>

Use the CIBoxBlur filter with default options to blur an image: <pre class="example-preformatted">coreimage=filter=CIBoxBlur@default </pre>

Use a filter chain with CISepiaTone at default values and CIVignetteEffect with its center at 100x100 and a radius of 50 pixels: <pre class="example-preformatted">coreimage=filter=CIBoxBlur@default#CIVignetteEf
100@inputRadius=50 </pre>

Use nullsrc and CIQRCodeGenerator to create a QR code for the FFmpeg homepage, given as complete and escaped command-line for Apple’s standard bash shell: <pre class="example-preformatted">ffmpeg -f lavfi -i nullsrc=s=100x100,coreimage=filter=CIQRCodeGenerator@inputMessage=ht
-frames:v 1 QRCode.png </pre>

 <h3 class="section">11.45 corr# TOC</h3>

Obtain the correlation between two input videos. This filter takes two input videos. Both input videos must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained per component, average, min and max correlation is printed through the logging system. The filter stores the calculated correlation of each frame in frame metadata. This filter also supports the framesync options. In the below example the input file <samp class="file">main.mpg</samp> being processed is compared with the reference file <samp class="file">ref.mpg</samp>.   <pre class="example-preformatted">ffmpeg -i main.mpg -i ref.mpg -lavfi corr -f null - </pre>

aspect ratio </dd> <dt><samp class="option">dar</samp></dt> <dd> input display aspect ratio, it is the same as (<var class="var">iw</var> / <var class="var">ih</var>) * <var class="var">sar</var> </dd> <dt><samp class="option">hsub</samp></dt> <dt><samp class="option">vsub</samp></dt> <dd> horizontal and vertical chroma subsample values. For example for the pixel format "yuv422p" <var class="var">hsub</var> is 2 and <var class="var">vsub</var> is 1. </dd> <dt><samp class="option">n</samp></dt> <dd> The number of the input frame, starting from 0. </dd> <dt><samp class="option">pos</samp></dt> <dd> the position in the file of the input frame, NAN if unknown; deprecated, do not use </dd> <dt><samp class="option">t</samp></dt> <dd> The timestamp expressed in seconds. It’s NAN if the input timestamp is unknown. </dd> </dl>

The expression for <var class="var">out_w</var> may depend on the value of <var class="var">out_h</var>, and the expression for <var class="var">out_h</var> may depend on <var class="var">out_w</var>, but they cannot depend on <var class="var">x</var> and <var class="var">y</var>, as <var class="var">x</var> and <var class="var">y</var> are evaluated after <var class="var">out_w</var> and <var class="var">out_h</var>. The <var class="var">x</var> and <var class="var">y</var> parameters specify the expressions for the position of the top-left corner of the output (non-cropped) area. They are evaluated for each frame. If the evaluated value is not valid, it is approximated to the nearest valid value. The expression for <var class="var">x</var> may depend on <var class="var">y</var>, and the expression for <var class="var">y</var> may depend on <var class="var">x</var>. <h4 class="subsection">11.47.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Crop area with size 100x100 at position (12,34). <pre class="example-preformatted">crop=100:100:12:34 </pre>

Using named options, the example above becomes: <pre class="example-preformatted">crop=w=100:h=100:x=12:y=34 </pre>

Crop the central input area with size 100x100: <pre class="example-preformatted">crop=100:100 </pre>

Crop the central input area with size 2/3 of the input video: <pre class="example-preformatted">crop=2/3*in_w:2/3*in_h </pre>

Crop the input video central square: <pre

class=”example-preformatted”>crop=out_w=in_h crop=in_h </pre>

Delimit the rectangle with the top-left corner placed at position 100:100 and the right-bottom corner corresponding to the right-bottom corner of the input image. <pre class=”example-preformatted”>crop=in_w-100:in_h-100:100:100 </pre>

Crop 10 pixels from the left and right borders, and 20 pixels from the top and bottom borders <pre class=”example-preformatted”>crop=in_w-2*10:in_h-2*20 </pre>

Keep only the bottom right quarter of the input image: <pre class=”example-preformatted”>crop=in_w/2:in_h/2:in_w/2:in_h/2 </pre>

Crop height for getting Greek harmony: <pre class=”example-preformatted”>crop=in_w:1/PHI*in_w </pre>

Apply trembling effect: <pre class=”example-preformatted”>crop=in_w/2:in_h/2:(in_w-out_w)/2+((in_w-out_w)/2)*sin(n/10):(in_h-out_h)/2 +((in_h-out_h)/2)*sin(n/7) </pre>

Apply erratic camera effect depending on timestamp: <pre class=”example-preformatted”>crop=in_w/2:in_h/2:(in_w-out_w)/2+((in_w-out_w)/2)*sin(t*10):(in_h-out_h)/2 +((in_h-out_h)/2)*sin(t*13) </pre>

Set x depending on the value of y: <pre class=”example-preformatted”>crop=in_w/2:in_h/2:y:10+10*sin(n/10) </pre>

 <h4 class=”subsection”>11.47.2 Commands# TOC</h4>

This filter supports the following commands: <dl class=”table”> <dt><samp class=”option”>w, out_w</samp></dt> <dt><samp class=”option”>h, out_h</samp></dt> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> Set width/height of the output video and the horizontal/vertical position in the input video. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h3 class=”section”>11.48 cropdetect# TOC</h3>

Auto-detect the crop size. It calculates the necessary

cropping parameters and prints the recommended parameters via the logging system. The detected dimensions correspond to the non-black or video area of the input video according to <var class=”var”>mode</var>. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>mode</samp></dt> <dd> Depending on <var class=”var”>mode</var> crop detection is based on either the mere black value of surrounding pixels or a combination of motion vectors and edge pixels. <dl class=”table”> <dt>‘<samp class=”samp”>black</samp>’</dt> <dd> Detect black pixels surrounding the playing video. For fine control use option <var class=”var”>limit</var>. </dd> <dt>‘<samp class=”samp”>mvedges</samp>’</dt> <dd> Detect the playing video by the motion vectors inside the video and scanning for edge pixels typically forming the border of a playing video. </dd> </dl>

</dd> <dt><samp class=”option”>limit</samp></dt> <dd> Set higher black value threshold, which can be optionally specified from nothing (0) to everything (255 for 8-bit based formats). An intensity value greater to the set value is considered non-black. It defaults to 24. You can also specify a value between 0.0 and 1.0 which will be scaled depending on the bitdepth of the pixel format. </dd> <dt><samp class=”option”>round</samp></dt> <dd> The value which the width/height should be divisible by. It defaults to 16. The offset is automatically adjusted to center the video. Use 2 to get only even dimensions (needed for 4:2:2 video). 16 is best when encoding to most video codecs. </dd> <dt><samp class=”option”>skip</samp></dt> <dd> Set the number of initial frames for which evaluation is skipped. Default is 2. Range is 0 to INT_MAX. </dd> <dt><samp class=”option”>reset_count, reset</samp></dt> <dd> Set the counter that determines after how many frames cropdetect will reset the previously detected largest video area and start over to detect the current optimal crop area. Default value is 0. This can be useful when channel logos distort the video area. 0 indicates ’never reset’, and returns the largest area encountered during playback. </dd> <dt><samp class=”option”>mv_threshold</samp></dt> <dd> Set motion in pixel units as threshold for motion detection. It defaults to 8. </dd> <dt><samp class=”option”>low</samp></dt> <dt><samp class=”option”>high</samp></dt> <dd> Set low and high threshold values used by the Canny thresholding algorithm. The high threshold selects the "strong" edge pixels, which are then connected through 8-connectivity with the "weak" edge pixels selected by the low threshold. <var class=”var”>low</var> and <var class=”var”>high</var> threshold values must be chosen in the range [0,1], and <var class=”var”>low</var> should be lesser or equal to <var class=”var”>high</var>. Default value for <var class=”var”>low</var> is <code class=”code”>5/255</code>, and default value for <var class=”var”>high</var> is <code class=”code”>15/255</code>.

</dd> </dl>

This filter supports the following commands: <dl class="table"> <dt><samp class="option">limit</samp></dt> <dd> The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. </dd> </dl>

 <h3 class="section">11.49 cue# TOC</h3>

Delay video filtering until a given wallclock timestamp. The filter first passes on <samp class="option">preroll</samp> amount of frames, then it buffers at most <samp class="option">buffer</samp> amount of frames and waits for the cue. After reaching the cue it forwards the buffered frames and also any subsequent frames coming in its input. The filter can be used synchronize the output of multiple ffmpeg processes for realtime output devices like decklink. By putting the delay in the filtering chain and pre-buffering frames the process can pass on data to output almost immediately after the target wallclock timestamp is reached. Perfect frame accuracy cannot be guaranteed, but the result is good enough for some use cases. <dl class="table"> <dt><samp class="option">cue</samp></dt> <dd> The cue timestamp expressed in a UNIX timestamp in microseconds. Default is 0. </dd> <dt><samp class="option">preroll</samp></dt> <dd> The duration of content

to pass on as preroll expressed in seconds. Default is 0. </dd> <dt><samp class="option">buffer</samp></dt> <dd> The maximum duration of content to buffer before waiting for the cue expressed in seconds. Default is 0. </dd> </dl>

 <h3 class="section">11.50 curves# TOC</h3>

Apply color adjustments using curves. This filter is similar to the Adobe Photoshop and GIMP curves tools. Each component (red, green and blue) has its values defined by <var class="var">N</var> key points tied from each other using a smooth curve. The x-axis represents the pixel values from the input frame, and the y-axis the new pixel values to be set for the output frame. By default, a component curve is defined by the two points <var class="var">(0;0)</var> and <var class="var">(1;1)</var>. This creates a straight line where each original pixel value is "adjusted" to its own value, which means no change to the image. The filter allows you to redefine these two points and add some more. A new curve will be defined to pass smoothly through all these new coordinates. The new defined points need to be strictly increasing over the x-axis, and their <var class="var">x</var> and <var class="var">y</var> values must be in the <var class="var">[0;1]</var> interval. The curve is formed by using a natural or monotonic cubic spline interpolation, depending on the <var class="var">interp</var> option (default: <code class="code">natural</code>). The <code class="code">natural</code> spline produces a smoother curve in general while the monotonic (<code class="code">pchip</code>) spline guarantees the transitions between the specified points to be monotonic. If the computed curves happened to go outside the vector spaces, the values will be clipped accordingly. The filter accepts the following options: <dl class="table"> <dt><samp class="option">preset</samp></dt> <dd> Select one of the available color presets. This option can be used in addition to the <samp class="option">r</samp>, <samp class="option">g</samp>, <samp class="option">b</samp> parameters; in this case, the later options takes priority on the preset values. Available presets are: <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dt>‘<samp class="samp">color_negative</samp>&rs
<dt>‘<samp class="samp">cross_process</samp>’</dt>
<dt>‘<samp class="samp">darker</samp>’</dt> <dt>‘<samp class="samp">increase_contrast</samp>’</dt> <dt>‘<samp class="samp">lighter</samp>’</dt> <dt>‘<samp class="samp">linear_contrast</samp>&
<dt>‘<samp class="samp">medium_contrast</samp>’</dt>
<dt>‘<samp class="samp">negative</samp>’</dt> <dt>‘<samp class="samp">strong_contrast</samp>’</dt> <dt>‘<samp class="samp">vintage</samp>’</dt> </dl> Default is <code

class=”code”>none</code>. </dd> <dt><samp class=”option”>master, m</samp></dt> <dd> Set the master key points. These points will define a second pass mapping. It is sometimes called a "luminance" or "value" mapping. It can be used with <samp class=”option”>r</samp>, <samp class=”option”>g</samp>, <samp class=”option”>b</samp> or <samp class=”option”>all</samp> since it acts like a post-processing LUT. </dd> <dt><samp class=”option”>red, r</samp></dt> <dd> Set the key points for the red component. </dd> <dt><samp class=”option”>green, g</samp></dt> <dd> Set the key points for the green component. </dd> <dt><samp class=”option”>blue, b</samp></dt> <dd> Set the key points for the blue component. </dd> <dt><samp class=”option”>all</samp></dt> <dd> Set the key points for all components (not including master). Can be used in addition to the other key points component options. In this case, the unset component(s) will fallback on this <samp class=”option”>all</samp> setting. </dd> <dt><samp class=”option”>psfile</samp></dt> <dd> Specify a Photoshop curves file (<code class=”code”>.acv</code>) to import the settings from. </dd> <dt><samp class=”option”>plot</samp></dt> <dd> Save Gnuplot script of the curves in specified file. </dd> <dt><samp class=”option”>interp</samp></dt> <dd> Specify the kind of interpolation. Available algorithms are: <dl class=”table”> <dt>‘<samp class=”samp”>natural</samp>’</dt> <dd> Natural cubic spline using a piece-wise cubic polynomial that is twice continuously differentiable. </dd> <dt>‘<samp class=”samp”>pchip</samp>’</dt> <dd> Monotonic cubic spline using a piecewise cubic Hermite interpolating polynomial (PCHIP). </dd> </dl>

</dd> </dl>

To avoid some filtergraph syntax conflicts, each key points list need to be defined using the following syntax: <code class=”code”>x0/y0 x1/y1 x2/y2 ...</code>. <h4 class=”subsection”>11.50.1 Commands# TOC</h4>

This filter supports same commands as options. <h4 class=”subsection”>11.50.2 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Increase slightly the middle level of blue: <pre class=”example-preformatted”>curves=blue='0/0 0.5/0.58 1/1' </pre>

Vintage effect: <pre class=”example-

preformatted”>curves=r='0/0.11 .42/.51 1/0.95':g='0/0 0.50/0.48 1/1':b='0/0.22 .49/.44 1/0.8' </pre> Here we obtain the following coordinates for each components: <dl class=”table”> <dt><var class=”var”>red</var></dt> <dd> <code class=”code”>(0;0.11) (0.42;0.51) (1;0.95)</code> </dd> <dt><var class=”var”>green</var></dt> <dd> <code class=”code”>(0;0) (0.50;0.48) (1;1)</code> </dd> <dt><var class=”var”>blue</var></dt> <dd> <code class=”code”>(0;0.22) (0.49;0.44) (1;0.80)</code> </dd> </dl>

The previous example can also be achieved with the associated built-in preset: <pre class=”example-preformatted”>curves=preset=vintage </pre>

Or simply: <pre class=”example-preformatted”>curves=vintage </pre>

Use a Photoshop preset and redefine the points of the green component: <pre class=”example-preformatted”>curves=psfile='MyCurvesPresets/purple.a 0.45/0.53 1/1' </pre>

Check out the curves of the <code class=”code”>cross_process</code> profile using <code class=”command”>ffmpeg</code> and <code class=”command”>gnuplot</code>: <pre class=”example-preformatted”>ffmpeg -f lavfi -i color -vf curves=cross_process:plot=/tmp/curves.plt -frames:v 1 -f null - gnuplot -p /tmp/curves.plt </pre>

 <h3 class="section">11.61 deinterlace_d3d12# TOC</h3>

Deinterlace the input video using D3D12 hardware-accelerated video processing. This filter uses the DirectX 12 Video Processor to perform deinterlacing on GPU, supporting both simple bob and driver-defined advanced (motion-adaptive) algorithms. It requires the input to be in <code class="code">d3d12</code> hardware pixel format. The filter automatically queries the hardware for the required number of temporal reference frames (if needed) and manages a frame queue to supply them. It accepts the following options: <dl class="table"> <dt><samp class="option">method</samp></dt> <dd> The deinterlacing method. It accepts one of the following values: <dl class="table"> <dt>‘<samp class="samp">default</samp>’</dt> <dd> Select the best deinterlacing method available on the hardware. If the driver supports <code class="code">custom</code>, that method is used; otherwise falls back to <code class="code">bob</code>. This is the default. </dd> <dt>‘<samp class="samp">bob</samp>’</dt> <dd> Bob deinterlacing. Each field is independently scaled to full frame height. Simple and fast, but may produce visible bob artifacts on moving content. </dd> <dt>‘<samp class="samp">custom</samp>’</dt> <dd> Driver-defined advanced deinterlacing. The exact algorithm is hardware-specific and typically employs motion-adaptive techniques with temporal reference frames for higher quality. </dd> </dl>

The default value is <code class="code">default</code>. </dd> <dt><samp class="option">mode</samp></dt> <dd> Specify the interlacing mode. It accepts one of the following values: <dl class="table"> <dt>‘<samp class="samp">frame</samp>’</dt> <dd> Send one frame for each frame. The output frame rate equals the input frame rate. This is the default. </dd> <dt>‘<samp class="samp">field</samp>’</dt> <dd> Send one frame for each field. The output frame rate is double the input frame rate. </dd> </dl>

The default value is <code class="code">frame</code>. </dd>

<dt><samp class=”option”>deint</samp></dt> <dd> Specify which frames to deinterlace. It accepts one of the following values: <dl class=”table”> <dt>‘<samp class=”samp”>all</samp>’</dt> <dd> Deinterlace all frames. This is the default. </dd> <dt>‘<samp class=”samp”>interlaced</samp>’</dt> <dd> Only deinterlace frames marked as interlaced; progressive frames are passed through unchanged. </dd> </dl>

The default value is <code class=”code”>all</code>. </dd> </dl>

 <h4 class=”subsection”>11.61.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Deinterlace an interlaced video using software decoding and the best available hardware deinterlacing method: <pre class=”example-preformatted”>ffmpeg -init_hw_device d3d12va=d3d12 -filter_hw_device d3d12 -i input.ts \ -vf "format=nv12,hwupload,deinterlace_d3d12=method=default,hwdownload,format=nv12" \ -c:v libx264 -crf 18 output.mp4 </pre>

Deinterlace at field rate (double the frame rate) using bob method with hardware decoding (full d3d12 pipeline): <pre class=”example-preformatted”>ffmpeg -hwaccel d3d12va -hwaccel_output_format d3d12 -i input.ts \ -vf "deinterlace_d3d12=method=bob:mode=field" \ -c:v h264_d3d12va output.mp4 </pre>

Deinterlace only interlaced frames, passing progressive frames through: <pre class=”example-preformatted”>ffmpeg -init_hw_device d3d12va=d3d12 -filter_hw_device d3d12 -i input.ts \ -vf "format=nv12,hwupload,deinterlace_d3d12=deint=interlaced,hwdownload,format=nv12" \ -c:v libx264 -crf 18 output.mp4 </pre>

 <h3 class=”section”>11.62 dejudder# TOC</h3>

Remove judder produced by partially interlaced telecined content. Judder can be introduced, for instance, by pullup filter. If the original source was partially telecined content then the output of <code class=”code”>pullup,dejudder</code> will have a variable frame rate. May change the recorded frame rate of the container. Aside from that change, this filter will not affect constant frame rate video. The option available in this filter is: <dl class=”table”> <dt><samp class=”option”>cycle</samp></dt> <dd> Specify the

length of the window over which the judder repeats. Accepts any integer greater than 1. Useful values are: <dl class="table"> <dt>‘<samp class="samp">4</samp>’</dt> <dd> If the original was telecined from 24 to 30 fps (Film to NTSC). </dd> <dt>‘<samp class="samp">5</samp>’</dt> <dd> If the original was telecined from 25 to 30 fps (PAL to NTSC). </dd> <dt>‘<samp class="samp">20</samp>’</dt> <dd> If a mixture of the two. </dd> </dl>

The default is ‘<samp class="samp">4</samp>’. </dd> </dl>

 <h3 class="section">11.63 delogo# TOC</h3>

Suppress a TV station logo by a simple interpolation of the surrounding pixels. Just set a rectangle covering the logo and watch it disappear (and sometimes something even uglier appear - your mileage may vary). It accepts the following parameters: <dl class="table"> <dt><samp class="option">x</samp></dt> <dt><samp class="option">y</samp></dt> <dd> Specify the top left corner coordinates of the logo. They must be specified. </dd> <dt><samp class="option">w</samp></dt> <dt><samp class="option">h</samp></dt> <dd> Specify the width and height of the logo to clear. They must be specified. </dd> <dt><samp class="option">show</samp></dt> <dd> When set to 1, a green rectangle is drawn on the screen to simplify finding the right <var class="var">x</var>, <var class="var">y</var>, <var class="var">w</var>, and <var class="var">h</var> parameters. The default value is 0. The rectangle is drawn on the outermost pixels which will be (partly) replaced with interpolated values. The values of the next pixels immediately outside this rectangle in each direction will be used to compute the interpolated pixel values inside the rectangle. </dd> </dl>

 <h4 class="subsection">11.63.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Set a rectangle covering the area with top left corner coordinates 0,0 and size 100x77: <pre class="example-preformatted">delogo=x=0:y=0:w=100:h=77 </pre>

 <h3 class="section">11.64 derain# <a class="anchor

hidden-xs”href=”#toc-derain” aria-hidden=”true”>TOC</h3>

Remove the rain in the input image/video by applying the derain methods based on convolutional neural networks. Supported models: <ul class=”itemize mark-bullet”> Recurrent Squeeze-and-Excitation Context Aggregation Net (RESCAN). See http://openaccess.thecvf.com/content_ECCV_2018/pa and-Excitation_Context_ECCV_2018_paper.pdf.

Training as well as model generation scripts are provided in the repository at <a class=”url” href=”https://github.com/XueweiMeng/derain_filter.git”>https://github.com/XueweiMeng/d The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>filter_type</samp></dt> <dd> Specify which filter to use. This option accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>derain</samp>’</dt> <dd> Derain filter. To conduct derain filter, you need to use a derain model. </dd> <dt>‘<samp class=”samp”>dehaze</samp>’</dt> <dd> Dehaze filter. To conduct dehaze filter, you need to use a dehaze model. </dd> </dl> Default value is ‘<samp class=”samp”>derain</samp>’. </dd> <dt><samp class=”option”>dnn_backend</samp></dt> <dd> Specify which DNN backend to use for model loading and execution. This option accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>tensorflow</samp>’</dt> <dd> TensorFlow backend. To enable this backend you need to install the TensorFlow for C library (see <a class=”url” href=”https://www.tensorflow.org/install/lang_c”>https://www.tensorflow.org/install/lang_c and configure FFmpeg with <code class=”code”>--enable-libtensorflow</code> </dd> </dl>

</dd> <dt><samp class=”option”>model</samp></dt> <dd> Set path to model file specifying network architecture and its parameters. Note that different backends use different file formats. TensorFlow can load files for only its format. </dd> </dl>

 <h3 class="section">11.72 dnn_processing# TOC</h3>

Do image processing with deep neural networks. It works together with another filter which converts the pixel format of the Frame to what the dnn network requires. The filter accepts the following options: <dl class="table"> <dt><samp class="option">dnn_backend</samp></dt> <dd> Specify which DNN backend to use for model loading and execution. This option accepts the following values: <dl class="table"> <dt>‘<samp class="samp">tensorflow</samp>’</dt> <dd> TensorFlow backend. To enable this backend you need to install the TensorFlow for C library (see <a class="url" href="https://www.tensorflow.org/install/lang_c">https://www and configure FFmpeg with <code class="code">--enable-libtensorflow</code> </dd> <dt>‘<samp class="samp">openvino</samp>’</dt> <dd> OpenVINO backend. To enable this backend you need to build and install the OpenVINO for C library (see https://github.com/openvinotoolkit/openvino/blob/master/build-instruction.md) and configure FFmpeg with <code class="code">--enable-libopenvino</code> (–extra-cflags=-I... –extra-ldflags=-L... might be needed if the header files and libraries are not installed into system path) </dd> <dt>‘<samp class="samp">torch</samp>’</dt> <dd> Libtorch backend. To enable this backend you need to build and install Libtorch for C++ library. Please download cxx11 ABI version (see https://pytorch.org/get-started/locally) and configure FFmpeg with <code class="code">--enable-libtorch --extra-cflags=-I/libtorch_root/libtorch/include --extra-cflags=-I/libtorch_root/libtorch/include/torch/csrc/api/include --extra-ldflags=-L/libtorch_root/libtorch/lib/</code> When FFm-

peg is built with CUDA support and the input frames use <code class=”code”>AV_PIX_FMT_CUDA</code> with an underlying pixel format of <code class=”code”>rgb0</code>, <code class=”code”>bgr0</code>, <code class=”code”>rgb24</code>, or <code class=”code”>bgr24</code>, the Torch backend maps GPU frame buffers directly into LibTorch CUDA tensors using zero-copy memory mapping. This avoids host-device PCIe transfers and can significantly reduce inference latency. The zero-copy path is selected automatically when the input format qualifies; no additional options are required. When the input format is not <code class=”code”>AV_PIX_FMT_CUDA</code>, the backend uses the standard CPU tensor path. </dd> <dt>‘<samp class=”samp”>onnx</samp>’</dt> <dd> ONNX Runtime backend. To enable this backend you need to install the ONNX Runtime library (see https://onnxruntime.ai/) and configure FFmpeg with <code class=”code”>--enable-libonnxruntime</code>. The current ONNX Runtime backend expects 4-D input and output tensors with NCHW layout and 32-bit floating-point element type (ONNX <code class=”code”>FLOAT</code>); models with integer or other element types (e.g. <code class=”code”>UINT8</code>) are not supported and will be rejected at load time. Models using NHWC layout or other ranks are not yet supported. Only single-input models are supported; the backend binds exactly one input tensor when running the model. The <samp class=”option”>input</samp> and <samp class=”option”>output</samp> options are optional for the ONNX Runtime backend; when they are omitted the backend resolves the tensor names from the session. Multiple output names may be supplied separated by ‘<samp class=”samp”>&</samp>’ (e.g. <samp class=”option”>output=out_a&out_b</samp>); however for <code class=”code”>dnn_processing</code> only the first output tensor is used for frame post-processing. The ONNX Runtime backend runs inference synchronously using a single inference request. The shared <samp class=”option”>async</samp> and <samp class=”option”>nireq</samp> options therefore have no effect for <code class=”code”>dnn_backend=onnx</code>; inference always runs synchronously regardless of their values. When FFmpeg is built with Direct3D 12 support and this build’s ONNX Runtime provides a working DirectML execution provider, setting <samp class=”option”>device=dml</samp> together with <code class=”code”>AV_PIX_FMT_D3D12</code> NV12 hardware frames as input (e.g. via <code class=”code”>-hwaccel d3d12va -hwaccel_output_format d3d12</code>) keeps frames in VRAM for the whole filter, from the decoder’s output through DNN inference and back out, without a host round-trip. Software-frame input retains the host I/O path. D3D12 input requires successful DirectML negotiation; unsupported hardware-input configurations fail during configuration. At runtime, <samp class=”file”>DirectML.dll</samp> and <samp class=”file”>d3dcompiler_47.dll</samp>

must be loadable from the application directory or System32. Currently, only single-channel (luma-only), <code class="code">FLOAT</code>/NCHW models with a <code class="code">[1,1,H,W]</code> output tensor and even input/output frame dimensions are supported; the chroma plane is copied or bilinearly upscaled on the GPU without going through the model. The output frames are D3D12 hardware frames, so they must either be consumed by a D3D12 encoder or downloaded explicitly with <code class="code">hwdownload,format=nv12</code>. </dd> </dl>

</dd> <dt><samp class="option">model</samp></dt> <dd> Set path to model file specifying network architecture and its parameters. Note that different backends use different file formats. TensorFlow, OpenVINO, Libtorch, and ONNX Runtime backends can load files for only their respective formats. </dd> <dt><samp class="option">input</samp></dt> <dd> Set the input name of the dnn network. Required for the TensorFlow backend; optional for the ONNX Runtime backend. </dd> <dt><samp class="option">output</samp></dt> <dd> Set the output name of the dnn network. To use async execution, set async (default: set). Roll back to sync execution if the backend does not support async. For tensorflow backend, you can set its configs with <samp class="option">sess_config</samp> options, please use tools/python/tf_sess_config.py to get the configs of TensorFlow backend for your system. </dd> <dt><samp class="option">async</samp></dt> <dd> Use DNN async inference (default: 1). When enabled, frames are submitted to the backend without blocking the caller. Supported by the Torch, OpenVINO, and TensorFlow backends; the ONNX Runtime backend ignores this option. </dd> <dt><samp class="option">nireq</samp></dt> <dd> Number of concurrent inference requests (default: 0, meaning auto). When set to 0, the backend automatically determines an appropriate number of requests. Higher values increase throughput by allowing multiple frames to be in flight simultaneously. </dd> <dt><samp class="option">batch_size</samp></dt> <dd> Number of frames to batch into a single inference request (default: 1). Values greater than 1 cause the backend to accumulate frames and concatenate them along the batch dimension before running the model. This can significantly increase throughput on GPUs at the cost of slightly higher per-frame latency. Currently supported by the OpenVINO and Torch backends. </dd> <dt><samp class="option">device</samp></dt> <dd> Set the device to run the model. For the ONNX Runtime backend this selects the execution provider: <code class="code">cpu</code> (default), <code class="code">cuda</code> (NVIDIA GPU), <code class="code">dml</code> (DirectML, Windows only) or <code class="code">vitisai</code> (AMD Ryzen AI NPU). </dd> <dt><samp class="option">device_id</samp></dt>

<dd> Set the device index used by GPU execution providers (e.g. <code class=”code”>cuda</code> or <code class=”code”>dml</code>) for the ONNX Runtime backend. Default is 0. </dd> <dt><samp class=”option”>threads_per_operation</samp></dt> <dd> ONNX Runtime backend only. Set the number of CPU threads used per ONNX Runtime operator when running with <code class=”code”>device=cpu</code>. Default is 0 (let ONNX Runtime choose automatically). Has no effect for GPU/NPU providers. </dd> </dl>

 <h4 class=”subsection”>11.72.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Remove rain in rgb24 frame with can.pb (see derain filter): <pre class=”example-preformatted”>./ffmpeg -i rain.jpg -vf format=rgb24,dnn_processing=dnn_backend=tensorflow:model=can.pb:input=x:output=y derain.jpg </pre>

Handle the Y channel with srcnn.pb (see sr filter) for frame with yuv420p (planar YUV formats supported): <pre class=”example-preformatted”>./ffmpeg -i 480p.jpg -vf format=yuv420p,scale=w=iw*2:h=ih*2,dnn_processing=dnn_backend=tensorflow:model=srcn -y srcnn.jpg </pre>

Handle the Y channel with espcn.pb (see sr filter), which changes frame size, for format yuv420p (planar YUV formats supported), please use tools/python/tf_sess_config.py to get the configs of TensorFlow backend for your system. <pre class=”example-preformatted”>./ffmpeg -i 480p.jpg -vf format=yuv420p,dnn_processing=dnn_backend= -y tmp.espcn.jpg </pre>

Perform zero-copy GPU inference with the Libtorch backend. Because there is currently no GPU-side filter to convert from YUV to RGB, <code class=”code”>hwupload</code> is used to upload CPU RGB frames into device memory. Once a GPU-side YUV-to-RGB filter becomes available, the <code class=”code”>hwupload</code> step will no longer be necessary and all frames can stay in device memory throughout the pipeline: <pre class=”example-preformatted”>./ffmpeg -init_hw_device cuda=cuda -filter_hw_device cuda -i input.mp4 \ -vf "format=rgb24,hwupload,dnn_processing=dnn_backend=torch:model=my_model.pt,hwdownload,form \ -y output.mp4 </pre>

Run a single-channel (luma-only) super-resolution model on D3D12 hardware frames with the ONNX Runtime backend, keeping frames in VRAM from decode through inference (Windows only, requires a build with Direct3D 12 support and <code class=”code”>--enable-libonnxruntime</code> against a DirectML-capable ONNX Runtime).

The D3D12 output frames are encoded directly by a D3D12 hardware encoder: <pre class=”example-preformatted”>./ffmpeg -hwaccel d3d12va -hwaccel_output_format d3d12 -i input.mp4 \ -vf dnn_processing=dnn_backend=onnx:model=sr_model.onnx:device=dml \ -c:v h264_d3d12va -bf 0 -y output.mp4 </pre>

Same as above, but download the result to software frames after inference so that a software encoder can be used: <pre class=”example-preformatted”>./ffmpeg -hwaccel d3d12va -hwaccel_output_format d3d12 -i input.mp4 \ -vf dnn_processing=dnn_backend=onnx:model=sr_model.onnx:device=dml,hwdownloa \ -y output.mp4 </pre>

Process rgb24 frames with a TorchScript model using the Libtorch backend: <pre class=”example-preformatted”>./ffmpeg -i input.jpg -vf format=rgb24,dnn_processing=dnn_backend=torch:model=my_model.pt output.jpg </pre>

Process rgb24 frames with the Libtorch backend using batch inference (four frames per request): <pre class=”example-preformatted”>./ffmpeg -i input.mp4 -vf format=rgb24,dnn_processing=dnn_backend=torch:model=my_mo -y output.mp4 </pre>

 <h3 class=”section”>11.73 drawbox# TOC</h3>

Draw a colored box on the input image. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> The expressions which specify the top left corner coordinates of the box. It defaults to 0. </dd> <dt><samp class=”option”>width, w</samp></dt> <dt><samp class=”option”>height, h</samp></dt> <dd> The expressions which specify the width and height of the box; if 0 they are interpreted as the input width and height. It defaults to 0. </dd> <dt><samp class=”option”>color, c</samp></dt> <dd> Specify the color of the box to write. For the general syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. If the special value <code class=”code”>invert</code> is used, the box edge color is the same as the video with inverted luma. </dd> <dt><samp class=”option”>thickness, t</samp></dt> <dd> The expression which sets the thickness of the box edge. A value of <code class=”code”>fill</code> will create a filled box. Default value is <code class=”code”>3</code>. See below for the list of accepted constants. </dd> <dt><samp class=”option”>replace</samp></dt> <dd> Applicable if the input has alpha. With value <code class=”code”>1</code>, the pixels of the painted

box will overwrite the video’s color and alpha pixels. Default is <code class="code">0</code>, which composites the box onto the input, leaving the video’s alpha intact. </dd> </dl>

The parameters for <var class="var">x</var>, <var class="var">y</var>, <var class="var">w</var> and <var class="var">h</var> and <var class="var">t</var> are expressions containing the following constants: <dl class="table"> <dt><samp class="option">dar</samp></dt> <dd> The input display aspect ratio, it is the same as (<var class="var">w</var> / <var class="var">h</var>) * <var class="var">sar</var>. </dd> <dt><samp class="option">hsub</samp></dt> <dt><samp class="option">vsub</samp></dt> <dd> horizontal and vertical chroma subsample values. For example for the pixel format "yuv422p" <var class="var">hsub</var> is 2 and <var class="var">vsub</var> is 1. </dd> <dt><samp class="option">in_h, ih</samp></dt> <dt><samp class="option">in_w, iw</samp></dt> <dd> The input width and height. </dd> <dt><samp class="option">sar</samp></dt> <dd> The input sample aspect ratio. </dd> <dt><samp class="option">x</samp></dt> <dt><samp class="option">y</samp></dt> <dd> The x and y offset coordinates where the box is drawn. </dd> <dt><samp class="option">w</samp></dt> <dt><samp class="option">h</samp></dt> <dd> The width and height of the drawn box. </dd> <dt><samp class="option">box_source</samp></dt> <dd> Box source can be set as side_data_detection_bboxes if you want to use box data in detection bboxes of side data. If <var class="var">box_source</var> is set, the <var class="var">x</var>, <var class="var">y</var>, <var class="var">width</var> and <var class="var">height</var> will be ignored and still use box data in detection bboxes of side data. So please do not use this parameter if you were not sure about the box source. </dd> <dt><samp class="option">t</samp></dt> <dd> The thickness of the drawn box. These constants allow the <var class="var">x</var>, <var class="var">y</var>, <var class="var">w</var>, <var class="var">h</var> and <var class="var">t</var> expressions to refer to each other, so you may for example specify <code class="code">y=x/dar</code> or <code class="code">h=w/dar</code>. </dd> </dl>

when right border is reached. </dd> <dt>‘<samp class=”samp”>replace</samp>’</dt
<dd> Replace old columns with new ones. </dd> <dt>‘<samp
class=”samp”>scroll</samp>’</dt> <dd> Scroll from right to
left. </dd> <dt>‘<samp class=”samp”>rscroll</samp>’</dt>
<dd> Scroll from left to right. </dd> <dt>‘<samp
class=”samp”>picture</samp>’</dt> <dd> Draw single picture.
</dd> </dl>

Default is <code class=”code”>frame</code>. </dd>
<dt><samp class=”option”>size</samp></dt> <dd> Set size of
graph video. For the syntax of this option, check the <a data-manual=”ffmpeg-
utils” href=”./ffmpeg-utils.html#video-size-syntax”>"Video size"
section in the ffmpeg-utils manual. The default value is <code
class=”code”>900x256</code>. </dd> <dt><samp class=”option”>rate,
r</samp></dt> <dd> Set the output frame rate. Default value is <code
class=”code”>25</code>. The foreground color expressions
can use the following variables: <dl class=”table”> <dt><samp
class=”option”>MIN</samp></dt> <dd> Minimal value of metadata
value. </dd> <dt><samp class=”option”>MAX</samp></dt>
<dd> Maximal value of metadata value. </dd> <dt><samp
class=”option”>VAL</samp></dt> <dd> Current metadata key value.
</dd> </dl>

The color is defined as 0xAABBGGRR. </dd> </dl>

Example using metadata from signalstats
filter: <pre class=”example-preformatted”>signalstats,drawgraph=lavfi.signalst
</pre>

Example using metadata from ebur128
filter: <pre class=”example-preformatted”>ebur128=metadata=1,adrawgraph=
120:max=5 </pre>

 <h3 class=”section”>11.75 drawgrid<span
class=”pull-right”><a class=”anchor hidden-xs” href=”#drawgrid” aria-
hidden=”true”># <a class=”anchor hidden-xs”href=”#toc-drawgrid”
aria-hidden=”true”>TOC</h3>

Draw a grid on the input image. It accepts the following parame-
ters: <dl class=”table”> <dt><samp class=”option”>x</samp></dt>
<dt><samp class=”option”>y</samp></dt> <dd> The expressions
which specify the coordinates of some point of grid intersection (meant

to configure offset). Both default to 0. </dd> <dt><samp class=”option”>width, w</samp></dt> <dt><samp class=”option”>height, h</samp></dt> <dd> The expressions which specify the width and height of the grid cell, if 0 they are interpreted as the input width and height, respectively, minus <code class=”code”>thickness</code>, so image gets framed. Default to 0. </dd> <dt><samp class=”option”>color, c</samp></dt> <dd> Specify the color of the grid. For the general syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. If the special value <code class=”code”>invert</code> is used, the grid color is the same as the video with inverted luma. </dd> <dt><samp class=”option”>thickness, t</samp></dt> <dd> The expression which sets the thickness of the grid line. Default value is <code class=”code”>1</code>. See below for the list of accepted constants. </dd> <dt><samp class=”option”>replace</samp></dt> <dd> Applicable if the input has alpha. With <code class=”code”>1</code> the pixels of the painted grid will overwrite the video’s color and alpha pixels. Default is <code class=”code”>0</code>, which composites the grid onto the input, leaving the video’s alpha intact. </dd> </dl>

The parameters for <var class=”var”>x</var>, <var class=”var”>y</var>, <var class=”var”>w</var> and <var class=”var”>h</var> and <var class=”var”>t</var> are expressions containing the following constants: <dl class=”table”> <dt><samp class=”option”>dar</samp></dt> <dd> The input display aspect ratio, it is the same as (<var class=”var”>w</var> / <var class=”var”>h</var>) * <var class=”var”>sar</var>. </dd> <dt><samp class=”option”>hsub</samp></dt> <dt><samp class=”option”>vsub</samp></dt> <dd> horizontal and vertical chroma subsample values. For example for the pixel format "yuv422p" <var class=”var”>hsub</var> is 2 and <var class=”var”>vsub</var> is 1. </dd> <dt><samp class=”option”>in_h, ih</samp></dt> <dt><samp class=”option”>in_w, iw</samp></dt> <dd> The input grid cell width and height. </dd> <dt><samp class=”option”>sar</samp></dt> <dd> The input sample aspect ratio. </dd> <dt><samp class=”option”>x</samp></dt> <dt><samp class=”option”>y</samp></dt> <dd> The x and y coordinates of some point of grid intersection (meant to configure offset). </dd> <dt><samp class=”option”>w</samp></dt> <dt><samp class=”option”>h</samp></dt> <dd> The width and height of the drawn cell. </dd> <dt><samp class=”option”>t</samp></dt> <dd> The thickness of the drawn cell. These constants allow the <var class=”var”>x</var>, <var class=”var”>y</var>, <var class=”var”>w</var>, <var class=”var”>h</var> and <var class=”var”>t</var> expressions to refer to each other, so you may for example specify <code class=”code”>y=x/dar</code> or <code class=”code”>h=w/dar</code>. </dd> </dl>

 <h4 class="subsection">11.75.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Draw a grid with cell 100x100 pixels, thickness 2 pixels, with color red and an opacity of 50%: <pre class="example-preformatted">drawgrid=width=100:height=100:thickness=2:color=red@0.5 </pre>

Draw a white 3x3 grid with an opacity of 50%: <pre class="example-preformatted">drawgrid=w=iw/3:h=ih/3:t=2:c=white@0.5 </pre>

 <h4 class="subsection">11.75.2 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class="section">11.76 drawtext# TOC</h3>

Draw a text string or text from a specified file on top of a video, using the libfreetype library. To enable compilation of this filter, you need to configure FFmpeg with <code class="code">--enable-libfreetype</code> and <code class="code">--enable-libharfbuzz</code>. To enable default font fallback and the <var class="var">font</var> option you need to configure FFmpeg with <code class="code">--enable-libfontconfig</code>. To enable the <var class="var">text_shaping</var> option, you need to configure FFmpeg with <code class="code">--enable-libfribidi</code>. <h4 class="subsection">11.76.1 Syntax# TOC</h4>

It accepts the following parameters:

<dl class="table">

<dt><samp class="option">box</samp></dt>

<dd> Used to draw a box around text using the background color.

The value must be either 1 (enable) or 0 (disable).

The default value of <var class=”var”>box</var> is 0.

</dd>

<dt><samp class=”option”>boxborderw</samp></dt>

<dd> Set the width of the border to be drawn around the box using <var class=”var”>boxcolor</var>.

The value must be specified using one of the following formats:

<ul class=”itemize mark-bullet”>

<code class=”code”>boxborderw=10</code> set the width of all the borders to 10

<code class=”code”>boxborderw=10|20</code> set the width of the top and bottom borders to 10

and the width of the left and right borders to 20

<code class=”code”>boxborderw=10|20|30</code> set the width of the top border to 10, the width

of the bottom border to 30 and the width of the left and right borders to 20

<code class=”code”>boxborderw=10|20|30|40</code> set the borders width to 10 (top), 20 (right),

30 (bottom), 40 (left)

The default value of <var class=”var”>boxborderw</var> is "0".

</dd>

<dt><samp class=”option”>boxcolor</samp></dt>

<dd> The color to be used for drawing box around text. For the syntax of this

option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual.

The default value of <var class=”var”>boxcolor</var> is "white".

</dd>

<dt><samp class=”option”>line_spacing</samp></dt>

<dd> Set the line spacing in pixels. The default value of <var class="var">line_spacing</var> is 0.

</dd>

<dt><samp class="option">text_align</samp></dt>

<dd> Set the vertical and horizontal alignment of the text with respect to the box boundaries.

The value is combination of flags, one for the vertical alignment (T=top,

M=middle, B=bottom) and one for the horizontal alignment (L=left, C=center, R=right).

Please note that tab characters are only supported with the left horizontal alignment.

</dd>

<dt><samp class="option">y_align</samp></dt>

<dd> Specify what the <var class="var">y</var> value is referred to. Possible values are:

<ul class="itemize mark-bullet">

<code class="code">text</code> the top of the highest glyph of the first text line is placed at <var class="var">y</var>

<code class="code">baseline</code> the baseline of the first text line is placed at <var class="var">y</var>

<code class="code">font</code> the baseline of the first text line is placed at <var class="var">y</var> plus the

ascent (in pixels) defined in the font metrics

The default value of <var class="var">y_align</var> is "text" for backward compatibility.

</dd>

<dt><samp class="option">borderw</samp></dt>

<dd> Set the width of the border to be drawn around the text using <var class="var">bordercolor</var>.

The default value of <var class="var">borderw</var> is 0.

</dd>

<dt><samp class="option">bordercolor</samp></dt>

<dd> Set the color to be used for drawing border around text. For the syntax of this

option, check the <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#color-syntax">"Color" section in the ffmpeg-utils manual.

The default value of <var class="var">bordercolor</var> is "black".

</dd>

<dt><samp class="option">expansion</samp></dt>

<dd> Select how the <var class="var">text</var> is expanded. Can be either <code class="code">none</code>,

<code class="code">strftime</code> (deprecated) or <code class="code">normal</code> (default). See the

Text expansion section below for details.

</dd>

<dt><samp class="option">basetime</samp></dt>

<dd> Set a start time for the count. Value is in microseconds. Only applied

in the deprecated <code class="code">strftime</code> expansion mode. To emulate in normal expansion

mode use the <code class="code">pts</code> function, supplying the start time (in seconds)

as the second argument.

</dd>

<dt><samp class="option">fix_bounds</samp></dt>

<dd> If true, check and fix text coords to avoid clipping.

</dd>

<dt><samp class="option">fontcolor</samp></dt>

<dd> The color to be used for drawing fonts. For the syntax of this option, check

the <a data-manual="ffmpeg-utils" href="./ffmpeg-utils.html#color-syntax">"Color" section in the ffmpeg-utils manual.

The default value of <var class="var">fontcolor</var> is "black".

</dd>

<dt><samp class="option">fontcolor_expr</samp></dt>

<dd> String which is expanded the same way as <var class="var">text</var> to obtain dynamic

<var class="var">fontcolor</var> value. By default this option has empty value and is not

processed. When this option is set, it overrides <var class="var">fontcolor</var> option.

</dd>

<dt><samp class="option">font</samp></dt>

<dd> The font family to be used for drawing text. By default Sans.

</dd>

<dt><samp class="option">fontfile</samp></dt>

<dd> The font file to be used for drawing text. The path must be included.

This parameter is mandatory if the fontconfig support is disabled.

</dd>

<dt><samp class="option">alpha</samp></dt>

<dd> Draw the text applying alpha blending. The value can

be a number between 0.0 and 1.0.

The expression accepts the same variables <var class="var">x, y</var> as well.

The default value is 1.

Please see <var class="var">fontcolor_expr</var>.

</dd>

<dt><samp class="option">fontsize</samp></dt>

<dd> The font size to be used for drawing text.

The default value of <var class="var">fontsize</var> is 16.

</dd>

<dt><samp class="option">text_shaping</samp></dt>

<dd> If set to 1, attempt to shape the text (for example, reverse the order of

right-to-left text and join Arabic characters) before drawing it.

Otherwise, just draw the text exactly as given.

By default 1 (if supported).

</dd>

<dt><samp class="option">ft_load_flags</samp></dt>

<dd> The flags to be used for loading the fonts.

The flags map the corresponding flags supported by libfreetype, and are

a combination of the following values:

<dl class="table">

<dt><var class="var">default</var></dt>

<dt><var class="var">no_scale</var></dt>

<dt><var class="var">no_hinting</var></dt>

<dt><var class="var">render</var></dt>

<dt><var class="var">no_bitmap</var></dt>

<dt><var class="var">vertical_layout</var></dt>

<dt><var class="var">force_autohint</var></dt>

<dt><var class="var">crop_bitmap</var></dt>

<dt><var class="var">pedantic</var></dt>

<dt><var class=”var”>ignore_global_advance_width</var></dt>

<dt><var class=”var”>no_recurse</var></dt>

<dt><var class=”var”>ignore_transform</var></dt>

<dt><var class=”var”>monochrome</var></dt>

<dt><var class=”var”>linear_design</var></dt>

<dt><var class=”var”>no_autohint</var></dt>

</dl>

Default value is "default".

For more information consult the documentation for the FT_LOAD_*

libfreetype flags.

</dd>

<dt><samp class=”option”>shadowcolor</samp></dt>

<dd> The color to be used for drawing a shadow behind the drawn text. For the

syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the

ffmpeg-utils manual.

The default value of <var class=”var”>shadowcolor</var> is "black".

</dd>

<dt><samp class=”option”>boxw</samp></dt>

<dd> Set the width of the box to be drawn around text.

The default value of <var class=”var”>boxw</var> is computed automatically to match the text width

</dd>

<dt><samp class=”option”>boxh</samp></dt>

<dd> Set the height of the box to be drawn around text.

The default value of <var class=”var”>boxh</var> is computed automatically to match the text height

</dd>

<dt><samp class=”option”>shadowx</samp></dt>

<dt><samp class=”option”>shadowy</samp></dt>

<dd> The x and y offsets for the text shadow position with respect to the

position of the text. They can be either positive or negative

values. The default value for both is "0".

</dd>

<dt><samp class=”option”>start_number</samp></dt>

<dd> The starting frame number for the n/frame_num variable. The default value

is "0".

</dd>

<dt><samp class=”option”>tabsize</samp></dt>

<dd> The size in number of spaces to use for rendering the tab.

Default value is 4.

</dd>

<dt><samp class=”option”>timecode</samp></dt>

<dd> Set the initial timecode representation in "hh:mm:ss[:;.]ff"

format. It can be used with or without text parameter. <var class=”var”>timecode_rate</var>

option must be specified.

</dd>

<dt><samp class=”option”>timecode_rate, rate, r</samp></dt>

<dd> Set the timecode frame rate (timecode only). Value will be rounded to nearest

integer. Minimum value is "1".

Drop-frame timecode is supported for frame rates 30 & 60.

</dd>

<dt><samp class=”option”>tc24hmax</samp></dt>

<dd> If set to 1, the output of the timecode option will wrap around at 24 hours.

Default is 0 (disabled).

</dd>

<dt><samp class=”option”>text</samp></dt>

<dd> The text string to be drawn. The text must be a sequence of UTF-8

encoded characters.

This parameter is mandatory if no file is specified with the parameter

<var class=”var”>textfile</var>.

</dd>

<dt><samp class=”option”>textfile</samp></dt>

<dd> A text file containing text to be drawn. The text must be a sequence

of UTF-8 encoded characters.

This parameter is mandatory if no text string is specified with the

parameter <var class=”var”>text</var>.

If both <var class=”var”>text</var> and <var class=”var”>textfile</var> are specified, an error is thrown.

</dd>

<dt><samp class=”option”>text_source</samp></dt>

<dd> Text source should be set as side_data_detection_bboxes if you want to use text data in

detection bboxes of side data.

If text source is set, <var class="var">text</var> and <var class="var">textfile</var> will be ignored and still use

text data in detection bboxes of side data. So please do not use this parameter

if you are not sure about the text source.

</dd>

<dt><samp class="option">reload</samp></dt>

<dd> The <var class="var">textfile</var> will be reloaded at specified frame interval.

Be sure to update <var class="var">textfile</var> atomically, or it may be read partially,

or even fail.

Range is 0 to INT_MAX. Default is 0.

</dd>

<dt><samp class="option">x</samp></dt>

<dt><samp class="option">y</samp></dt>

<dd> The expressions which specify the offsets where text will be drawn

within the video frame. They are relative to the top/left border of the

output image.

The default value of <var class="var">x</var> and <var class="var">y</var> is "0".

See below for the list of accepted constants and functions.

</dd>

</dl>

The parameters for <var class="var">x</var> and <var class="var">y</var> are expressions containing the

following constants and functions:

<dl class="table">

<dt><samp class=”option”>dar</samp></dt>

<dd> input display aspect ratio, it is the same as (<var class=”var”>w</var> / <var class=”var”>h</var>) * <var class=”var”>sar</var>

</dd>

<dt><samp class=”option”>hsub</samp></dt>

<dt><samp class=”option”>vsub</samp></dt>

<dd> horizontal and vertical chroma subsample values. For example for the

pixel format "yuv422p" <var class=”var”>hsub</var> is 2 and <var class=”var”>vsub</var> is 1.

</dd>

<dt><samp class=”option”>line_h, lh</samp></dt>

<dd> the height of each text line

</dd>

<dt><samp class=”option”>main_h, h, H</samp></dt>

<dd> the input height

</dd>

<dt><samp class=”option”>main_w, w, W</samp></dt>

<dd> the input width

</dd>

<dt><samp class=”option”>max_glyph_a, ascent</samp></dt>

<dd> the maximum distance from the baseline to the highest/upper grid

coordinate used to place a glyph outline point, for all the rendered

glyphs.

It is a positive value, due to the grid’s orientation with the Y axis

upwards.

</dd>
<dt><samp class="option">max_glyph_d, descent</samp></dt>
<dd> the maximum distance from the baseline to the lowest grid coordinate used to place a glyph outline point, for all the rendered glyphs.
This is a negative value, due to the grid’s orientation, with the Y axis upwards.

</dd>
<dt><samp class="option">max_glyph_h</samp></dt>
<dd> maximum glyph height, that is the maximum height for all the glyphs contained in the rendered text, it is equivalent to <var class="var">ascent</var>
-
<var class="var">descent</var>.

</dd>
<dt><samp class="option">max_glyph_w</samp></dt>
<dd> maximum glyph width, that is the maximum width for all the glyphs contained in the rendered text

</dd>
<dt><samp class="option">font_a</samp></dt>
<dd> the ascent size defined in the font metrics

</dd>
<dt><samp class="option">font_d</samp></dt>
<dd> the descent size defined in the font metrics

</dd>
<dt><samp class="option">top_a</samp></dt>
<dd> the maximum ascender of the glyphs of the first text line

</dd>

<dt><samp class="option">bottom_d</samp></dt>

<dd> the maximum descender of the glyphs of the last text line

</dd>

<dt><samp class="option">n</samp></dt>

<dd> the number of input frame, starting from 0

</dd>

<dt><samp class="option">rand(min, max)</samp></dt>

<dd> return a random number included between <var class="var">min</var> and <var class="var">max</var>

</dd>

<dt><samp class="option">sar</samp></dt>

<dd> The input sample aspect ratio.

</dd>

<dt><samp class="option">t</samp></dt>

<dd> timestamp expressed in seconds, NAN if the input timestamp is unknown

</dd>

<dt><samp class="option">text_h, th</samp></dt>

<dd> the height of the rendered text

</dd>

<dt><samp class="option">text_w, tw</samp></dt>

<dd> the width of the rendered text

</dd>

<dt><samp class=”option”>x</samp></dt>

<dt><samp class=”option”>y</samp></dt>

<dd> the x and y offset coordinates where the text is drawn.

These parameters allow the <var class=”var”>x</var> and <var class=”var”>y</var> expressions to refer

to each other, so you can for example specify <code class=”code”>y=x/dar</code>.

</dd>

<dt><samp class=”option”>pict_type</samp></dt>

<dd> A one character description of the current frame’s picture type.

</dd>

<dt><samp class=”option”>pkt_pos</samp></dt>

<dd> The current packet’s position in the input file or stream

(in bytes, from the start of the input). A value of -1 indicates

this info is not available.

</dd>

<dt><samp class=”option”>duration</samp></dt>

<dd> The current packet’s duration, in seconds.

</dd>

<dt><samp class=”option”>pkt_size</samp></dt>

<dd> The current packet’s size (in bytes).

</dd>

</dl>

 <h4 class=”subsection”>11.76.2 Text expansion# TOC</h4>

If <samp class="option">expansion</samp> is set to <code class="code">strftime</code>, the filter recognizes

sequences accepted by the <code class="code">strftime</code> C function in the provided

text and expands them accordingly. Check the documentation of

<code class="code">strftime</code>. This feature is deprecated in favor of <code class="code">normal</code>

expansion with the <code class="code">gmtime</code> or <code class="code">localtime</code> expansion

functions.

If <samp class="option">expansion</samp> is set to <code class="code">none</code>, the text is printed verbatim.

If <samp class="option">expansion</samp> is set to <code class="code">normal</code> (which is the default),

the following expansion mechanism is used.

The backslash character ‘<samp class="samp">\</samp>’, followed by any character, always expands to

the second character.

Sequences of the form <code class="code">%{...}</code> are expanded. The text between the

braces is a function name, possibly followed by arguments separated by ’:’.

If the arguments contain special characters or delimiters (’:’ or ’}’),

they should be escaped.

Note that they probably must also be escaped as the value for the <samp class="option">text</samp>

option in the filter argument string and as the filter argument in the

filtergraph description, and possibly also for the shell, that makes up to four

levels of escaping; using a text file with the <samp class="option">textfile</samp> option avoids

these problems.

The following functions are available:

<dl class="table">

<dt><code class="command">expr, e</code></dt>

<dd> The expression evaluation result.

It must take one argument specifying the expression to be evaluated,

which accepts the same constants and functions as the <var class="var">x</var> and

<var class="var">y</var> values. Note that not all constants should be used, for

example the text size is not known when evaluating the expression, so

the constants <var class="var">text_w</var> and <var class="var">text_h</var> will have an undefined

value.

</dd>

<dt><code class="command">expr_int_format, eif</code></dt>

<dd> Evaluate the expression’s value and output as formatted integer.

The first argument is the expression to be evaluated, just as for the <var class="var">expr</var> function.

The second argument specifies the output format. Allowed values are ‘<samp class="samp">x</samp>’,

‘<samp class="samp">X</samp>’, ‘<samp class="samp">d</samp>’ and ‘<samp class="samp">u</samp>’. They are treated exactly as in the

<code class="code">printf</code> function.

The third parameter is optional and sets the number of positions taken by the output.

It can be used to add padding with zeros from the left.

</dd>

<dt><code class="command">gmtime</code></dt>

<dd> The time at which the filter is running, expressed in UTC.

It can accept an argument: a <code class="code">strftime</code> C function format string.

The format string is extended to support the variable <var class="var">%[1-6]N</var>

which prints fractions of the second with optionally specified number of digits.

</dd>

<dt><code class="command">localtime</code></dt>

<dd> The time at which the filter is running, expressed in the local time zone.

It can accept an argument: a <code class="code">strftime</code> C function format string.

The format string is extended to support the variable <var class="var">%[1-6]N</var>

which prints fractions of the second with optionally specified number of digits.

</dd>

<dt><code class="command">metadata</code></dt>

<dd> Frame metadata. Takes one or two arguments.

The first argument is mandatory and specifies the metadata key.

The second argument is optional and specifies a default value, used when the

metadata key is not found or empty.

Available metadata can be identified by inspecting entries

starting with TAG included within each frame section

printed by running <code class=”code”>ffprobe -show_frames</code>.

String metadata generated in filters leading to

the drawtext filter are also available.

</dd>

<dt><code class=”command”>n, frame_num</code></dt>

<dd> The frame number, starting from 0.

</dd>

<dt><code class=”command”>pict_type</code></dt>

<dd> A one character description of the current picture type.

</dd>

<dt><code class=”command”>pts</code></dt>

<dd> The timestamp of the current frame.

It can take up to three arguments.

The first argument is the format of the timestamp; it defaults to <code class=”code”>flt</code>

for seconds as a decimal number with microsecond accuracy; <code class=”code”>hms</code> stands

for a formatted <var class=”var”>[-]HH:MM:SS.mmm</var> timestamp with millisecond accuracy.

<code class=”code”>gmtime</code> stands for the timestamp of the frame formatted as UTC time;

<code class=”code”>localtime</code> stands for the timestamp of the frame formatted as

local time zone time.

The second argument is an offset added to the timestamp.

If the format is set to <code class="code">hms</code>, a third argument <code class="code">24HH</code> may be

supplied to present the hour part of the formatted timestamp in 24h format

(00-23).

If the format is set to <code class="code">localtime</code> or <code class="code">gmtime</code>, a third

argument may be supplied: a <code class="code">strftime</code> C function format string.

By default, <var class="var">YYYY-MM-DD HH:MM:SS</var> format will be used.

</dd>

</dl>

 <h4 class="subsection">11.76.3 Commands# TOC</h4>

This filter supports altering parameters via commands: <dl class="table"> <dt><samp class="option">reinit</samp></dt> <dd> Alter existing filter parameters. Syntax for the argument is the same as for filter invocation, e.g.   <pre class="example-preformatted">fontsize=56:fontcolor=green:text='Hello World' </pre>

Full filter invocation with sendcmd would look like this: <pre class="example-preformatted">sendcmd=c='56.0 drawtext reinit fontsize=56\:fontcolor=green\:text=Hello\\ World' </pre>

If the entire argument can’t be parsed or applied as valid values then the filter will continue with its existing parameters. </dd> </dl>

The following options are also supported as commands: <ul class="itemize mark-bullet"> x y alpha fontsize fontcolor boxcolor bordercolor shadowcolor box boxw boxh boxborderw line_spacing text_align shadowx shadowy borderw

 <h4 class="subsection">11.76.4 Examples<a class="anchor hidden-xs" href="#Examples-

72” aria-hidden=”true”># TOC</h4>

<ul class=”itemize mark-bullet”> Draw "Test Text" with font FreeSerif, using the default values for the optional parameters.

 <pre class=”example-preformatted”>drawtext="fontfile=/usr/share/fonts/true
text='Test Text'" </pre>

Draw ’Test Text’ with font FreeSerif of size 24 at position x=100 and y=50 (counting from the top-left corner of the screen), text is yellow with a red box around it. Both the text and the box have an opacity of 20%.

 <pre class=”example-preformatted”>drawtext="fontfile=/usr/share/fonts/true
text='Test Text':\ x=100: y=50: fontsize=24: fontcolor=yellow@0.2: box=1:
boxcolor=red@0.2" </pre>

Note that the double quotes are not necessary if spaces are not used within the parameter list. Show the text at the center of the video frame: <pre class=”example-preformatted”>drawtext="fontsize=30:fontfile=FreeSerif.ttf:text='hello world':x=(w-text_w)/2:y=(h-text_h)/2" </pre>

Show the text at a random position, switching to a new position every 30 seconds: <pre class=”example-preformatted”>drawtext="fontsize=30:fontfile=FreeSerif.ttf:text='hello world':x=if(eq(mod(t\,30)\,0)\,rand(0\,(w-text_w))\,x):y=if(eq(mod(t\,30)\,0)\,rand(0\,(h-text_h))\,y)" </pre>

Show a text line sliding from right to left in the last row of the video frame. The file <samp class=”file”>LONG_LINE</samp> is assumed to contain a single line with no newlines. <pre class=”example-preformatted”>drawtext="fontsize=15:fontfile=FreeSerif.ttf:text=LONG_LINE:y=h-line_h:x=-50*t" </pre>

Show the content of file <samp class=”file”>CREDITS</samp> off the bottom of the frame and scroll up. <pre class=”example-preformatted”>drawtext="fontsize=20:fontfile=FreeSerif.ttf:textfile=CREDITS:y=h-20*t" </pre>

Draw a single green letter "g", at the center of the input video. The glyph baseline is placed at half screen height. <pre class=”example-preformatted”>drawtext="fontsize=60:fontfile=FreeSerif.ttf:fo
max_glyph_w)/2:y=h/2-ascent" </pre>

Show text for 1 second every 3 seconds: <pre class=”example-preformatted”>drawtext="fontfile=FreeSerif.ttf:fontcolor=white:x=100:y=x/dar:enable
</pre>

Use fontconfig to set the font. Note that the colons need to be escaped.

 <pre class=”example-preformatted”>drawtext='fontfile=Linux Libertine O-40\\:style=Semibold:text=FFmpeg' </pre>

Draw "Test Text" with font size dependent on height of the video. <pre class=”example-preformatted”>drawtext="text='Test Text': fontsize=h/30: x=(w-text_w)/2: y=(h-text_h*2)" </pre>

Print the date of a real-time encoding (see documentation for the <code class=”code”>strftime</code> C function): <pre class=”example-preformatted”>drawtext='fontfile=FreeSans.ttf:text=%{localtime\:%a %b %d %Y}' </pre>

Show text fading in and out (appearing/disappearing): <pre class=”example-preformatted”>#!/bin/sh DS=1.0 # display start DE=10.0 # display end FID=1.5 # fade in duration FOD=5 # fade out duration ffplay -f lavfi "color,drawtext=text=TEST:fontsize=50:fontfile=FreeSerif.ttf:fontcolor_
clip(255*(1*between(t\\, $DS + $FID\\, $DE - $FOD) + ((t - $DS)/$FID)*between(t\\, $DS\\, $DS + $FID) + (-(t - $DE)/$FOD)*between(t\\, $DE - $FOD\\, $DE))\\, 0\\, 255) \\\\: x\\\\: 2 }" </pre>

Horizontally align multiple separate texts. Note that <samp class=”option”>max_glyph_a</samp> and the <samp class=”option”>fontsize</samp> value are included in the <samp class=”option”>y</samp> offset. <pre class=”example-preformatted”>drawtext=fontfile=FreeSans.ttf:text=DOG:fontsize=
max_glyph_a, drawtext=fontfile=FreeSans.ttf:text=cow:fontsize=24:x=80:y=20+24-max_glyph_a </pre>

Plot special <var class=”var”>lavf.image2dec.source_basename</var> metadata onto each frame if such metadata exists. Otherwise, plot the string "NA". Note that image2 demuxer must have option <samp class=”option”>-export_path_metadata 1</samp> for the special metadata fields to be available for filters. <pre class=”example-preformatted”>drawtext="fontsize=20:fontcolor=white:fontfile=FreeSans.ttf:text='%{metadata\:lavf.ir
</pre>

Example of first several lines of <code class="code">hint</code> file for <code class="code">relative</code> mode: <pre class="example-preformatted">0,0 - # first frame 1,0 - # second frame, use third's frame top field and second's frame bottom field 1,0 - # third frame,

use fourth's frame top field and third's frame bottom field 1,0 - 0,0 - 0,0 - 1,0 - 1,0 - 1,0 - 0,0 - 0,0 - 1,0 - 1,0 - 1,0 - 0,0 - </pre>

 <h3 class="section">11.93 fieldmatch# TOC</h3>

Field matching filter for inverse telecine. It is meant to reconstruct the progressive frames from a telecined stream. The filter does not drop duplicated frames, so to achieve a complete inverse telecine <code class="code">fieldmatch</code> needs to be followed by a decimation filter such as decimate in the filtergraph. The separation of the field matching and the decimation is notably motivated by the possibility of inserting a de-interlacing filter fallback between the two. If the source has mixed telecined and real interlaced content, <code class="code">fieldmatch</code> will not be able to match fields for the interlaced parts. But these remaining combed frames will be marked as interlaced, and thus can be de-interlaced by a later filter such as yadif before decimation. In addition to the various configuration options, <code class="code">fieldmatch</code> can take an optional second stream, activated through the <samp class="option">ppsrc</samp> option. If enabled, the frames reconstruction will be based on the fields and frames from this second stream. This allows the first input to be pre-processed in order to help the various algorithms of the filter, while keeping the output lossless (assuming the fields are matched properly). Typically, a field-aware denoiser, or brightness/contrast adjustments can help. Note that this filter uses the same algorithms as TIVTC/TFM (AviSynth project) and VIVTC/VFM (VapourSynth project). The later is a light clone of TFM from which <code class="code">fieldmatch</code> is based on. While the semantic and usage are very close, some behaviour and options names can differ. The decimate filter currently only works for constant frame rate input. If your input has mixed telecined (30fps) and progressive content with a lower framerate like 24fps use the following filterchain to produce the necessary cfr stream: <code class="code">dejudder,fps=30000/1001,fieldmatch,decimate</code>. The filter accepts the following options: <dl class="table"> <dt><samp class="option">order</samp></dt> <dd> Specify the assumed field order of the input stream. Available values are: <dl class="table"> <dt>‘<samp class="samp">auto</samp>’</dt> <dd> Auto detect parity (use FFmpeg’s internal parity value). </dd> <dt>‘<samp class="samp">bff</samp>’</dt> <dd> Assume bottom field first. </dd> <dt>‘<samp class="samp">tff</samp>’</dt> <dd> Assume top field first. </dd> </dl>

Note that it is sometimes recommended not to trust the parity announced by the stream. Default value is <var class="var">auto</var>. </dd> <dt><samp class="option">mode</samp></dt> <dd> Set the matching mode or strategy to use. <samp class="option">pc</samp> mode is the safest in the sense that it won’t risk creating jerkiness due to duplicate frames when possible, but if there are bad edits or blended fields it will end up outputting combed frames when a good match might actually exist. On the other hand, <samp class="option">pcn_ub</samp> mode is the most risky in terms of creating jerkiness, but will almost always find a good frame if there is one. The other values are all somewhere in between <samp class="option">pc</samp> and <samp class="option">pcn_ub</samp> in terms of risking jerkiness and creating duplicate frames versus finding good matches in sections with bad edits, orphaned fields, blended fields, etc. More details about p/c/n/u/b are available in p/c/n/u/b meaning section. Available values are: <dl class="table"> <dt>‘<samp class="samp">pc</samp>’</dt> <dd> 2-way matching (p/c) </dd> <dt>‘<samp class="samp">pc_n</samp>’</dt> <dd> 2-way matching, and trying 3rd match if still combed (p/c + n) </dd> <dt>‘<samp class="samp">pc_u</samp>’</dt> <dd> 2-way matching, and trying 3rd match (same order) if still combed (p/c + u) </dd> <dt>‘<samp class="samp">pc_n_ub</samp>’</dt> <dd> 2-way matching, trying 3rd match if still combed, and trying 4th/5th matches if still combed (p/c + n + u/b) </dd> <dt>‘<samp class="samp">pcn</samp>’</dt> <dd> 3-way matching (p/c/n) </dd> <dt>‘<samp class="samp">pcn_ub</samp>’</dt> <dd> 3-way matching, and trying 4th/5th matches if all 3 of the original matches are detected as combed (p/c/n + u/b) </dd> </dl>

The parenthesis at the end indicate the matches that would be used for that mode assuming <samp class="option">order</samp>=<var class="var">tff</var> (and <samp class="option">field</samp> on <var class="var">auto</var> or <var class="var">top</var>). In terms of speed <samp class="option">pc</samp> mode is by far the fastest and <samp class="option">pcn_ub</samp> is the slowest. Default value is <var class="var">pc_n</var>. </dd> <dt><samp class="option">ppsrc</samp></dt> <dd> Mark the main input stream as a pre-processed input, and enable the secondary input stream as the clean source to pick the fields from. See the filter introduction for more details. It is similar to the <samp class="option">clip2</samp> feature from VFM/TFM. Default value is <code class="code">0</code> (disabled). </dd> <dt><samp class="option">field</samp></dt> <dd> Set the field to match from. It is recommended to set this to the same value as <samp class="option">order</samp> unless you experience matching failures with that setting. In certain circumstances changing the field that is used to match from can have a large impact on matching perfor-

mance. Available values are: <dl class="table"> <dt>‘<samp class="samp">auto</samp>’</dt> <dd> Automatic (same value as <samp class="option">order</samp>). </dd> <dt>‘<samp class="samp">bottom</samp>’</dt> <dd> Match from the bottom field. </dd> <dt>‘<samp class="samp">top</samp>’</dt> <dd> Match from the top field. </dd> </dl>

Default value is <var class="var">auto</var>. </dd> <dt><samp class="option">mchroma</samp></dt> <dd> Set whether or not chroma is included during the match comparisons. In most cases it is recommended to leave this enabled. You should set this to <code class="code">0</code> only if your clip has bad chroma problems such as heavy rainbowing or other artifacts. Setting this to <code class="code">0</code> could also be used to speed things up at the cost of some accuracy. Default value is <code class="code">1</code>. </dd> <dt><samp class="option">y0</samp></dt> <dt><samp class="option">y1</samp></dt> <dd> These define an exclusion band which excludes the lines between <samp class="option">y0</samp> and <samp class="option">y1</samp> from being included in the field matching decision. An exclusion band can be used to ignore subtitles, a logo, or other things that may interfere with the matching. <samp class="option">y0</samp> sets the starting scan line and <samp class="option">y1</samp> sets the ending line; all lines in between <samp class="option">y0</samp> and <samp class="option">y1</samp> (including <samp class="option">y0</samp> and <samp class="option">y1</samp>) will be ignored. Setting <samp class="option">y0</samp> and <samp class="option">y1</samp> to the same value will disable the feature. <samp class="option">y0</samp> and <samp class="option">y1</samp> defaults to <code class="code">0</code>. </dd> <dt><samp class="option">scthresh</samp></dt> <dd> Set the scene change detection threshold as a percentage of maximum change on the luma plane. Good values are in the <code class="code">[8.0, 14.0]</code> range. Scene change detection is only relevant in case <samp class="option">combmatch</samp>=<var class="var">sc</var>. The range for <samp class="option">scthresh</samp> is <code class="code">[0.0, 100.0]</code>. Default value is <code class="code">12.0</code>. </dd> <dt><samp class="option">combmatch</samp></dt> <dd> When <samp class="option">combatch</samp> is not <var class="var">none</var>, <code class="code">fieldmatch</code> will take into account the combed scores of matches when deciding what match to use as the final match. Available values are: <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dd> No final matching based on combed scores. </dd> <dt>‘<samp class="samp">sc</samp>’</dt> <dd> Combed scores are only used when a scene change is detected. </dd> <dt>‘<samp class="samp">full</samp>’</dt> <dd> Use combed scores all the time. </dd> </dl>

Default is <var class=”var”>sc</var>. </dd> <dt><samp class=”option”>combdbg</samp></dt> <dd> Force <code class=”code”>fieldmatch</code> to calculate the combed metrics for certain matches and print them. This setting is known as <samp class=”option”>micout</samp> in TFM/VFM vocabulary. Available values are: <dl class=”table”> <dt>‘<samp class=”samp”>none</samp>’</dt> <dd> No forced calculation. </dd> <dt>‘<samp class=”samp”>pcn</samp>’</dt> <dd> Force p/c/n calculations. </dd> <dt>‘<samp class=”samp”>pcnub</samp>’</dt> <dd> Force p/c/n/u/b calculations. </dd> </dl>

Default value is <var class=”var”>none</var>. </dd> <dt><samp class=”option”>cthresh</samp></dt> <dd> This is the area combing threshold used for combed frame detection. This essentially controls how "strong" or "visible" combing must be to be detected. Larger values mean combing must be more visible and smaller values mean combing can be less visible or strong and still be detected. Valid settings are from <code class=”code”>-1</code> (every pixel will be detected as combed) to <code class=”code”>255</code> (no pixel will be detected as combed). This is basically a pixel difference value. A good range is <code class=”code”>[8, 12]</code>. Default value is <code class=”code”>9</code>. </dd> <dt><samp class=”option”>chroma</samp></dt> <dd> Sets whether or not chroma is considered in the combed frame decision. Only disable this if your source has chroma problems (rainbowing, etc.) that are causing problems for the combed frame detection with chroma enabled. Actually, using <samp class=”option”>chroma</samp>=<var class=”var”>0</var> is usually more reliable, except for the case where there is chroma only combing in the source. Default value is <code class=”code”>0</code>. </dd> <dt><samp class=”option”>blockx</samp></dt> <dt><samp class=”option”>blocky</samp></dt> <dd> Respectively set the x-axis and y-axis size of the window used during combed frame detection. This has to do with the size of the area in which <samp class=”option”>combpel</samp> pixels are required to be detected as combed for a frame to be declared combed. See the <samp class=”option”>combpel</samp> parameter description for more info. Possible values are any number that is a power of 2 starting at 4 and going up to 512. Default value is <code class=”code”>16</code>. </dd> <dt><samp class=”option”>combpel</samp></dt> <dd> The number of combed pixels inside any of the <samp class=”option”>blocky</samp> by <samp class=”option”>blockx</samp> size blocks on the frame for the frame to be detected as combed. While <samp class=”option”>cthresh</samp> controls how "visible" the combing must be, this setting controls "how much" combing there must be in any localized area (a window defined by the <samp class=”option”>blockx</samp> and <samp class=”option”>blocky</samp> settings) on the frame. Minimum value is

<code class="code">0</code> and maximum is <code class="code">blocky x blockx</code> (at which point no frames will ever be detected as combed). This setting is known as <samp class="option">MI</samp> in TFM/VFM vocabulary. Default value is <code class="code">80</code>. </dd> </dl>

 <h4 class="subsection">11.93.1 p/c/n/u/b meaning# TOC</h4>

 <h4 class="subsubsection">11.93.1.1 p/c/n# TOC</h4>

We assume the following telecined stream: <pre class="example-preformatted">Top fields: 1 2 2 3 4 Bottom fields: 1 2 3 4 4 </pre>

The numbers correspond to the progressive frame the fields relate to. Here, the first two frames are progressive, the 3rd and 4th are combed, and so on. When <code class="code">fieldmatch</code> is configured to run a matching from bottom (<samp class="option">field</samp>=<var class="var">bottom</var>) this is how this input stream get transformed: <pre class="example-preformatted">Input stream: T 1 2 2 3 4 B 1 2 3 4 4 <-- matching reference

Matches: c c n n c

Output stream: T 1 2 3 4 4 B 1 2 3 4 4 </pre>

As a result of the field matching, we can see that some frames get duplicated. To perform a complete inverse telecine, you need to rely on a decimation filter after this operation. See for instance the decimate filter. The same operation now matching from top fields (<samp class="option">field</samp>=<var class="var">top</var>) looks like this: <pre class="example-preformatted">Input stream: T 1 2 2 3 4 <-- matching reference B 1 2 3 4 4

Matches: c c p p c

Output stream: T 1 2 2 3 4 B 1 2 2 3 4 </pre>

In these examples, we can see what <var class="var">p</var>, <var class="var">c</var> and <var class="var">n</var> mean; basically, they refer to the frame and field of the opposite parity: <ul class="itemize mark-bullet"> <var class="var">p</var> matches the field of the

opposite parity in the previous frame <var class=”var”>c</var> matches the field of the opposite parity in the current frame <var class=”var”>n</var> matches the field of the opposite parity in the next frame

 <h4 class=”subsubsection”>11.93.1.2 u/b# TOC</h4>

The <var class=”var”>u</var> and <var class=”var”>b</var> matching are a bit special in the sense that they match from the opposite parity flag. In the following examples, we assume that we are currently matching the 2nd frame (Top:2, bottom:2). According to the match, a ’x’ is placed above and below each matched fields. With bottom matching (<samp class=”option”>field</samp>=<var class=”var”>bottom</var>): <pre class=”example-preformatted”>Match: c p n b u

x x x x x Top 1 2 2 1 2 2 1 2 2 1 2 2 1 2 2 Bottom 1 2 3 1 2 3 1 2 3 1 2 3 1 2 3 x x x x x

Output frames: 2 1 2 2 2 2 2 2 1 3 </pre>

With top matching (<samp class=”option”>field</samp>=<var class=”var”>top</var>): <pre class=”example-preformatted”>Match: c p n b u

x x x x x Top 1 2 2 1 2 2 1 2 2 1 2 2 1 2 2 Bottom 1 2 3 1 2 3 1 2 3 1 2 3 1 2 3 x x x x x

Output frames: 2 2 2 1 2 2 1 3 2 2 </pre>

 <h4 class=”subsection”>11.93.2 Examples# TOC</h4>

Simple IVTC of a top field first telecined stream: <pre class=”example-preformatted”>fieldmatch=order=tff:combmatch=none, decimate </pre>

Advanced IVTC, with fallback on yadif for still combed frames: <pre class=”example-preformatted”>fieldmatch=order=tff:combmatch=full, yadif=deint=interlaced, decimate </pre>

 <h3 class=”section”>11.94 fieldorder# TOC</h3>

Transform the field order of the input video. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>order</samp></dt> <dd> The output field order. Valid values are <var class=”var”>tff</var> for top field first or <var class=”var”>bff</var> for bottom field first. </dd> </dl>

The default value is ‘<samp class=”samp”>tff</samp>’. The transformation is done by shifting the picture content up or down by one line, and filling the remaining line with appropriate picture content. This method is consistent with most broadcast field order converters. If the input video is not flagged as being interlaced, or it is already flagged as being of the required output field order, then this filter does not alter the incoming video. It is very useful when converting to or from PAL DV material, which is bottom field first. For example: <pre class=”example-preformatted”>ffmpeg -i in.vob -vf "fieldorder=bff" out.dv </pre>

 <h3 class=”section”>11.95 fillborders# TOC</h3>

Fill borders of the input video, without changing video stream dimensions. Sometimes video can have garbage at the four edges and you may not want to crop video input to keep size multiple of some number. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>left</samp></dt> <dd> Number of pixels to fill from left border. </dd> <dt><samp class=”option”>right</samp></dt> <dd> Number of pixels to fill from right border. </dd> <dt><samp class=”option”>top</samp></dt> <dd> Number of pixels to fill from top border. </dd> <dt><samp class=”option”>bottom</samp></dt> <dd> Number of pixels to fill from bottom border. </dd> <dt><samp class=”option”>mode</samp></dt> <dd> Set fill mode. It accepts the following values: <dl class=”table”> <dt>‘<samp class=”samp”>smear</samp>’</dt> <dd> fill pixels using outermost pixels </dd> <dt>‘<samp class=”samp”>mirror</samp>’</dt> <dd> fill pixels using mirroring (half sample symmetric) </dd> <dt>‘<samp class=”samp”>fixed</samp>’</dt> <dd> fill pixels with constant value </dd> <dt>‘<samp class=”samp”>reflect</samp>’</dt> <dd> fill pixels using reflecting (whole sample symmetric) </dd> <dt>‘<samp class=”samp”>wrap</samp>’</dt> <dd> fill pixels using wrapping </dd> <dt>‘<samp class=”samp”>fade</samp>’</dt> <dd> fade pixels to constant value </dd> <dt>‘<samp class=”samp”>margins</samp>’</dt> <dd> fill pixels at top and bottom with weighted averages pixels near borders </dd> </dl>

Default is <var class=”var”>smear</var>. </dd> <dt><samp class=”option”>color</samp></dt> <dd> Set color for pixels in fixed or fade mode. Default is <var class=”var”>black</var>. </dd> </dl>

 <h4 class=”subsection”>11.95.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class=”section”>11.96 find_rect# TOC</h3>

Find a rectangular object in the input video. The object to search for must be specified as a gray8 image specified with the <samp class=”option”>object</samp> option. For each possible match, a score is computed. If the score reaches the specified threshold, the object is considered found. If the input video contains multiple instances of the object, the filter will find only one of them. When an object is found, the following metadata entries are set in the matching frame: <dl class=”table”> <dt><samp class=”option”>lavfi.rect.w</samp></dt> <dd> width of object </dd> <dt><samp class=”option”>lavfi.rect.h</samp></dt> <dd> height of object </dd> <dt><samp class=”option”>lavfi.rect.x</samp></dt> <dd> x position of object </dd> <dt><samp class=”option”>lavfi.rect.y</samp></dt> <dd> y position of object </dd> <dt><samp class=”option”>lavfi.rect.score</samp></dt> <dd> match score of the found object </dd> </dl>

It accepts the following options: <dl class=”table”> <dt><samp class=”option”>object</samp></dt> <dd> Filepath of the object image, needs to be in gray8. </dd> <dt><samp class=”option”>threshold</samp></dt> <dd> Detection threshold, expressed as a decimal number in the range 0-1. A threshold value of 0.01 means only exact matches, a threshold of 0.99 means almost everything matches. Default value is 0.5. </dd> <dt><samp class=”option”>mipmaps</samp></dt> <dd> Number of mipmaps, default is 3. </dd> <dt><samp class=”option”>xmin, ymin, xmax, ymax</samp></dt> <dd> Specifies the rectangle in which to search. </dd> <dt><samp class=”option”>discard</samp></dt> <dd> Discard frames where object is not detected. Default is disabled. </dd> </dl>

 <h4 class=”subsection”>11.96.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Cover a rectangular object by the supplied image of a given video using <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -i file.ts -vf find_rect=newref.pgm,cover_rect=cover.jpg:mode=cover new.mkv </pre>

Find the position of an object in each frame using <code class="command">ffprobe</code> and write it to a log file: <pre class="example-preformatted">ffprobe -f lavfi movie=test.mp4,find_rect=object=object.pgm:threshold=0.3 \ -show_entries frame=pkt_pts_time:frame_tags=lavfi.rect.x,lavfi.rect.y \ -of csv -o find_rect.csv </pre>

 <h3 class="section">11.97 floodfill# TOC</h3>

Flood area with values of same pixel components with another values. It accepts the following options: <dl class="table"> <dt><samp class="option">x</samp></dt> <dd> Set pixel x coordinate. </dd> <dt><samp class="option">y</samp></dt> <dd> Set pixel y coordinate. </dd> <dt><samp class="option">s0</samp></dt> <dd> Set source #0 component value. </dd> <dt><samp class="option">s1</samp></dt> <dd> Set source #1 component value. </dd> <dt><samp class="option">s2</samp></dt> <dd> Set source #2 component value. </dd> <dt><samp class="option">s3</samp></dt> <dd> Set source #3 component value. </dd> <dt><samp class="option">d0</samp></dt> <dd> Set destination #0 component value. </dd> <dt><samp class="option">d1</samp></dt> <dd> Set destination #1 component value. </dd> <dt><samp class="option">d2</samp></dt> <dd> Set destination #2 component value. </dd> <dt><samp class="option">d3</samp></dt> <dd> Set destination #3 component value. </dd> </dl>

 <h3 class="section">11.104 framestep# TOC</h3>

Select one frame every N-th frame. This filter accepts the following option: <dl class="table"> <dt><samp class="option">step</samp></dt> <dd> Select frame after every <code class="code">step</code> frames. Allowed values are positive integers higher than 0. Default value is <code class="code">1</code>. </dd> </dl>

 <h3 class="section">11.105 freezedetect# TOC</h3>

Detect frozen video. This filter logs a message and sets frame metadata when it detects that the input video has no significant change in content during a specified duration. Video freeze detection calculates the mean average absolute difference of all the components of video frames and compares it to a noise floor. The printed times and duration are expressed in seconds. The <code class="code">lavfi.freezedetect.freeze_start</code> metadata key is set on the first frame whose timestamp equals or exceeds the detection duration and it contains the timestamp of the first frame of the freeze. The <code class="code">lavfi.freezedetect.freeze_duration</code> and <code class="code">lavfi.freezedetect.freeze_end</code> metadata keys are set on the first frame after the freeze. The filter accepts the following options: <dl class="table"> <dt><samp class="option">noise, n</samp></dt> <dd> Set noise tolerance. Can be specified in dB (in case "dB" is appended to the specified value) or as a difference ratio between 0 and 1. Default is -60dB, or 0.001. </dd> <dt><samp class="option">duration, d</samp></dt> <dd> Set freeze duration until notification (default is 2 seconds). </dd> </dl>

 <h3 class="section">11.106 freezeframes# TOC</h3>

Freeze video frames. This filter freezes video frames using frame from 2nd input. The filter accepts the following options: <dl class="table"> <dt><samp class="option">first</samp></dt> <dd> Set number of first frame from which to start freeze. </dd> <dt><samp class="option">last</samp></dt> <dd> Set number of last frame from which to end freeze. </dd> <dt><samp class="option">replace</samp></dt> <dd> Set number of frame from 2nd input which will be used instead of replaced frames. </dd> </dl>

 <h3 class="section">11.107 frei0r# TOC</h3>

Apply a frei0r effect to the input video. To enable the compilation of this filter, you need to install the frei0r header and configure FFmpeg with <code class="code">--enable-frei0r</code>. It accepts the following parameters: <dl class="table"> <dt><samp class="option">filter_name</samp></dt> <dd> The name of the frei0r effect to load. If the environment variable <code

class=”env”>FREI0R_PATH</code> is defined, the frei0r effect is searched for in each of the directories specified by the colon-separated list in <code class=”env”>FREI0R_PATH</code>. Otherwise, the standard frei0r paths are searched, in this order: <samp class=”file”>HOME/.frei0r-1/lib/</samp>, <samp class=”file”>/usr/local/lib/frei0r-1/</samp>, <samp class=”file”>/usr/lib/frei0r-1/</samp>. </dd> <dt><samp class=”option”>filter_params</samp></dt> <dd> A ’|’-separated list of parameters to pass to the frei0r effect. </dd> </dl>

A frei0r effect parameter can be a boolean (its value is either "y" or "n"), a double, a color (specified as <var class=”var”>R</var>/<var class=”var”>G</var>/<var class=”var”>B</var>, where <var class=”var”>R</var>, <var class=”var”>G</var>, and <var class=”var”>B</var> are floating point numbers between 0.0 and 1.0, inclusive) or a color description as specified in the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual, a position (specified as <var class=”var”>X</var>/<var class=”var”>Y</var>, where <var class=”var”>X</var> and <var class=”var”>Y</var> are floating point numbers) and/or a string. The number and types of parameters depend on the loaded effect. If an effect parameter is not specified, the default value is set. <h4 class=”subsection”>11.107.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply the distort0r effect, setting the first two double parameters: <pre class=”example-preformatted”>frei0r=filter_name=distort0r:filter_params=0.5|0.01 </pre>

Apply the colordistance effect, taking a color as the first parameter: <pre class=”example-preformatted”>frei0r=colordistance:0.2/0.3/0.4 frei0r=colordistance:violet frei0r=colordistance:0x112233 </pre>

Apply the perspective effect, specifying the top left and top right image positions: <pre class=”example-preformatted”>frei0r=perspective:0.2/0.2|0.8/0.2 </pre>

For more information, see http://frei0r.dyne.org <h4 class=”subsection”>11.107.2 Commands# TOC</h4>

This filter supports the <samp class=”option”>filter_params</samp> option as commands. <h3 class=”section”>11.108 fspp#

TOC</h3>

Apply fast and simple postprocessing. It is a faster version of spp. It splits (I)DCT into horizontal/vertical passes. Unlike the simple post- processing filter, one of them is performed once per block, not per pixel. This allows for much higher speed. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>quality</samp></dt> <dd> Set quality. This option defines the number of levels for averaging. It accepts an integer in the range 4-5. Default value is <code class=”code”>4</code>. </dd> <dt><samp class=”option”>qp</samp></dt> <dd> Force a constant quantization parameter. It accepts an integer in range 0-63. If not set, the filter will use the QP from the video stream (if available). </dd> <dt><samp class=”option”>strength</samp></dt> <dd> Set filter strength. It accepts an integer in range -15 to 32. Lower values mean more details but also more artifacts, while higher values make the image smoother but also blurrier. Default value is <code class=”code”>0</code> − PSNR optimal. </dd> <dt><samp class=”option”>use_bframe_qp</samp></dt> <dd> Enable the use of the QP from the B-Frames if set to <code class=”code”>1</code>. Using this option may cause flicker since the B-Frames have often larger QP. Default is <code class=”code”>0</code> (not enabled). </dd> </dl>

 <h3 class=”section”>11.109 fsync# TOC</h3>

Synchronize video frames with an external mapping from a file. For each input PTS given in the map file it either drops or creates as many frames as necessary to recreate the sequence of output frames given in the map file. This filter is useful to recreate the output frames of a framerate conversion by the fps filter, recorded into a map file using the ffmpeg option <code class=”code”>-stats_mux_pre</code>, and do further processing to the corresponding frames e.g. quality comparison. Each line of the map file must contain three items per input frame, the input PTS (decimal), the output PTS (decimal) and the output TIMEBASE (decimal/decimal), separated by a space. This file format corresponds to the output of <code class=”code”>-stats_mux_pre_fmt="{ptsi} {pts} {tb}"</code>. The filter assumes the map file is sorted by increasing input PTS. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>file, f</samp></dt> <dd> The filename of the map file to be used. </dd> </dl>

Example: <pre class=”example-preformatted”># Convert a video to 25 fps and record a MAP_FILE file with the default format of this filter ffmpeg -i INPUT -vf fps=fps=25 -stats_mux_pre MAP_FILE

-stats_mux_pre_fmt "{ptsi} {pts} {tb}" OUTPUT

Sort MAP_FILE by increasing input PTS sort -n MAP_FILE

Use INPUT, OUTPUT and the MAP_FILE from above to compare the corresponding frames in INPUT and OUTPUT via SSIM ffmpeg -i INPUT -i OUTPUT -filter_complex '[0:v]fsync=file=MAP_FILE[ref];[1:v][ref]ssim' -f null - </pre>

 <h3 class="section">11.110 gainmap# TOC</h3>

Compute an HDR gain map from two renditions of the same image, as defined by ISO 21496-1. The first input is the base rendition (typically SDR), and the second input is the alternate rendition (typically HDR). Both must have the same dimensions. Outputs a gain map, as either ‘<samp class="samp">gbrpf32</samp>’ or ‘<samp class="samp">grayf32</samp>’ depending on the chosen <samp class="option">mode</samp>. <dl class="table"> <dt><samp class="option">mode</samp></dt> <dd> Controls what quantity the gain map is computed against. The accepted values are: <dl class="table"> <dt>‘<samp class="samp">rgb</samp>’</dt> <dd> One gain map channel per component. </dd> <dt>‘<samp class="samp">luma</samp>’</dt> <dd> A single gain map channel, computed from the luma. </dd> <dt>‘<samp class="samp">maxrgb</samp>’</dt> <dd> A single gain map channel, computed from ‘<samp class="samp">max(R, G, B)</samp>’. </dd> </dl>

Default is ‘<samp class="samp">rgb</samp>’. </dd> <dt><samp class="option">colorspace</samp></dt> <dd> Chooses which colorspace to compute the gain map in. The accepted values are: <dl class="table"> <dt>‘<samp class="samp">base</samp>’</dt> <dd> The base rendition’s colorspace. </dd> <dt>‘<samp class="samp">alternate</samp>’</dt> <dd> The alternate rendition’s colorspace. </dd> </dl>

Default is ‘<samp class="samp">base</samp>’. </dd> <dt><samp class="option">min</samp></dt> <dt><samp class="option">max</samp></dt> <dd> Bounds on the encoded gain (log2). If unspecified, these will be measured from the frame. </dd> <dt><samp class="option">gamma</samp></dt> <dd> Encoding gamma of the resulting gain map. If unspecified, this will be optimized for the frame in question. Setting this to <code class="code">1.0</code> will produce a linear gain map, which may be more efficient in some applications. </dd> <dt><samp class="option">base_offset</samp></dt> <dt><samp class="option">alt_offset</samp></dt> <dd> Offset to prevent numer-

ical instability near zero. Both default to <code class=”code”>1/64</code>. </dd> <dt><samp class=”option”>base_nits</samp></dt> <dt><samp class=”option”>alt_nits</samp></dt> <dd> Override the reference luminance of the input, in nits. If unspecified, uses the values from the input metadata. </dd> </dl>

The <code class=”code”>gainmap</code> filter also supports the framesync options. <h4 class=”subsection”>11.110.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Compute a gain map between an SDR and an HDR version of the same image: <pre class=”example-preformatted”>ffmpeg -i $sdr -i $hdr -filter_complex "[0:v][1:v]gainmap" $out </pre>

 <h3 class=”section”>11.111 gblur# TOC</h3>

Apply Gaussian blur filter. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>sigma</samp></dt> <dd> Set horizontal sigma, standard deviation of Gaussian blur. Default is <code class=”code”>0.5</code>. </dd> <dt><samp class=”option”>steps</samp></dt> <dd> Set number of steps for Gaussian approximation. Default is <code class=”code”>1</code>. </dd> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes to filter. By default all planes are filtered. </dd> <dt><samp class=”option”>sigmaV</samp></dt> <dd> Set vertical sigma, if negative it will be same as <code class=”code”>sigma</code>. Default is <code class=”code”>-1</code>. </dd> </dl>

 <h4 class=”subsection”>11.111.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class=”section”>11.112 geq# TOC</h3>

Apply generic equation to each pixel. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>lum_expr, lum</samp></dt> <dd> Set the luma expression. </dd> <dt><samp class=”option”>cb_expr, cb</samp></dt>

<dd> Set the chrominance blue expression. </dd> <dt><samp class=”option”>cr_expr, cr</samp></dt> <dd> Set the chrominance red expression. </dd> <dt><samp class=”option”>alpha_expr, a</samp></dt> <dd> Set the alpha expression. </dd> <dt><samp class=”option”>red_expr, r</samp></dt> <dd> Set the red expression. </dd> <dt><samp class=”option”>green_expr, g</samp></dt> <dd> Set the green expression. </dd> <dt><samp class=”option”>blue_expr, b</samp></dt> <dd> Set the blue expression. </dd> </dl>

The colorspace is selected according to the specified options. If one of the <samp class=”option”>lum_expr</samp>, <samp class=”option”>cb_expr</samp>, or <samp class=”option”>cr_expr</samp> options is specified, the filter will automatically select a YCbCr colorspace. If one of the <samp class=”option”>red_expr</samp>, <samp class=”option”>green_expr</samp>, or <samp class=”option”>blue_expr</samp> options is specified, it will select an RGB colorspace. If one of the chrominance expression is not defined, it falls back on the other one. If no alpha expression is specified it will evaluate to opaque value. If none of chrominance expressions are specified, they will evaluate to the luma expression. The expressions can use the following variables and functions: <dl class=”table”> <dt><samp class=”option”>N</samp></dt> <dd> The sequential number of the filtered frame, starting from <code class=”code”>0</code>. </dd> <dt><samp class=”option”>X</samp></dt> <dt><samp class=”option”>Y</samp></dt> <dd> The coordinates of the current sample. </dd> <dt><samp class=”option”>W</samp></dt> <dt><samp class=”option”>H</samp></dt> <dd> The width and height of the image. </dd> <dt><samp class=”option”>SW</samp></dt> <dt><samp class=”option”>SH</samp></dt> <dd> Width and height scale depending on the currently filtered plane. It is the ratio between the corresponding luma plane number of pixels and the current plane ones. E.g. for YUV4:2:0 the values are <code class=”code”>1,1</code> for the luma plane, and <code class=”code”>0.5,0.5</code> for chroma planes. </dd> <dt><samp class=”option”>T</samp></dt> <dd> Time of the current frame, expressed in seconds. </dd> <dt><samp class=”option”>p(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class=”var”>x</var>,<var class=”var”>y</var>) of the current plane. </dd> <dt><samp class=”option”>lum(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class=”var”>x</var>,<var class=”var”>y</var>) of the luma plane. </dd> <dt><samp class=”option”>cb(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class=”var”>x</var>,<var class=”var”>y</var>) of the blue-difference chroma plane. Return 0 if there is no such plane. </dd> <dt><samp class=”option”>cr(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class=”var”>x</var>,<var class=”var”>y</var>) of

the red-difference chroma plane. Return 0 if there is no such plane. </dd> <dt><samp class="option">r(x, y)</samp></dt> <dt><samp class="option">g(x, y)</samp></dt> <dt><samp class="option">b(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the red/green/blue component. Return 0 if there is no such component. </dd> <dt><samp class="option">alpha(x, y)</samp></dt> <dd> Return the value of the pixel at location (<var class="var">x</var>,<var class="var">y</var>) of the alpha plane. Return 0 if there is no such plane. </dd> <dt><samp class="option">psum(x,y), lumsum(x, y), cbsum(x,y), crsum(x,y), rsum(x,y), gsum(x,y), bsum(x,y), alphasum(x,y)</samp></dt> <dd> Sum of sample values in the rectangle from (0,0) to (x,y), this allows obtaining sums of samples within a rectangle. See the functions without the sum postfix. </dd> <dt><samp class="option">interpolation</samp></dt> <dd> Set one of interpolation methods: <dl class="table"> <dt><samp class="option">nearest, n</samp></dt> <dt><samp class="option">bilinear, b</samp></dt> </dl> Default is bilinear. </dd> </dl>

For functions, if <var class="var">x</var> and <var class="var">y</var> are outside the area, the value will be automatically clipped to the closer edge. Please note that this filter can use multiple threads in which case each slice will have its own expression state. If you want to use only a single expression state because your expressions depend on previous state then you should limit the number of filter threads to 1. <h4 class="subsection">11.112.1 Examples# TOC</h4>

<ul class="itemize mark-bullet"> Flip the image horizontally: <pre class="example-preformatted">geq=p(W-X\,Y) </pre>

Generate a bidimensional sine wave, with angle <code class="code">PI/3</code> and a wavelength of 100 pixels: <pre class="example-preformatted">geq=128 + 100*sin(2*(PI/100)*(cos(PI/3)*(X-50*T) + sin(PI/3)*Y)):128:128 </pre>

Generate a fancy enigmatic moving light: <pre class="example-preformatted">nullsrc=s=256x256,geq=random(1)/hypot(X-cos(N*0.07)*W/2-W/2\,Y-sin(N*0.09)*H/2-H/2)^2*1000000*sin(N*0.02):128:128 </pre>

Generate a quick emboss effect: <pre class="example-preformatted">format=gray,geq=lum_expr='(p(X,Y)+(256-p(X-4,Y-4)))/2' </pre>

Modify RGB components depending on pixel position: <div

class=”example”> <pre class=”example-preformatted”>geq=r='X/W*r(X,Y)':g='(1-X/W)*g(X,Y)':b='(H-Y)/H*b(X,Y)' </pre>

Create a radial gradient that is the same size as the input (also see the vignette filter): <pre class=”example-preformatted”>geq=lum=255*gauss((X/W-0.5)*3)*gauss((Y/H-0.5)*3)/gauss(0)/gauss(0),format=gray </pre>

 <h3 class=”section”>11.113 gradfun# TOC</h3>

Fix the banding artifacts that are sometimes introduced into nearly flat regions by truncation to 8-bit color depth. Interpolate the gradients that should go where the bands are, and dither them. It is designed for playback only. Do not use it prior to lossy compression, because compression tends to lose the dither and bring back the bands. It accepts the following parameters: <dl class=”table”> <dt><samp class=”option”>strength</samp></dt> <dd> The maximum amount by which the filter will change any one pixel. This is also the threshold for detecting nearly flat regions. Acceptable values range from .51 to 64; the default value is 1.2. Out-of-range values will be clipped to the valid range. </dd> <dt><samp class=”option”>radius</samp></dt> <dd> The neighborhood to fit the gradient to. A larger radius makes for smoother gradients, but also prevents the filter from modifying the pixels near detailed regions. Acceptable values are 8-32; the default value is 16. Out-of-range values will be clipped to the valid range. </dd> </dl>

Alternatively, the options can be specified as a flat string: <var class=”var”>strength</var>[:<var class=”var”>radius</var>] <h4 class=”subsection”>11.113.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply the filter with a <code class=”code”>3.5</code> strength and radius of <code class=”code”>8</code>: <pre class=”example-preformatted”>gradfun=3.5:8 </pre>

Specify radius, omitting the strength (which will fall-back to the default value): <pre class=”example-preformatted”>gradfun=radius=8 </pre>

 <h3 class=”section”>11.118 haldclut# TOC</h3>

Apply a Hald CLUT to a video stream. First input is the video stream to process, and second one is the Hald CLUT. The Hald CLUT input can be a simple picture or a complete video stream. The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>clut</samp></dt> <dd> Set which CLUT video frames will be processed from second input stream, can be <var class=”var”>first</var> or <var class=”var”>all</var>. Default is <var class=”var”>all</var>. </dd> <dt><samp class=”option”>shortest</samp></dt> <dd> Force termination when the shortest input terminates. Default is <code class=”code”>0</code>. </dd> <dt><samp class=”option”>repeatlast</samp></dt> <dd> Continue applying the last CLUT after the end of the stream. A value of <code class=”code”>0</code> disable the filter after the last frame of the CLUT is reached. Default is <code class=”code”>1</code>. </dd> </dl>

<code class=”code”>haldclut</code> also has the same interpolation options as lut3d (both filters share the same internals). This filter also supports the framesync options. More information about the Hald CLUT can be found on Eskil Steenberg’s website (Hald CLUT author) at <a class=”url” href=”http://www.quelsolaar.com/technology/clut.html”>http://www.quelsolaar.com/technology/clut.html< <h4 class=”subsection”>11.118.1 Commands# TOC</h4>

This filter supports the <code class=”code”>interp</code> option as commands.

 <h4 class="subsection">11.118.2 Workflow examples# TOC</h4>

 <h4 class="subsubsection">11.118.2.1 Hald CLUT video stream# TOC</h4>

Generate an identity Hald CLUT stream altered with various effects: <pre class="example-preformatted">ffmpeg -f lavfi -i haldclutsrc=8 -vf "hue=H=2*PI*t:s=sin(2*PI*t)+1, curves=cross_process" -t 10 -c:v ffv1 clut.nut </pre>

Note: make sure you use a lossless codec. Then use it with <code class="code">haldclut</code> to apply it on some random stream: <pre class="example-preformatted">ffmpeg -f lavfi -i mandelbrot -i clut.nut -filter_complex '[0][1] haldclut' -t 20 mandelclut.mkv </pre>

The Hald CLUT will be applied to the 10 first seconds (duration of <samp class="file">clut.nut</samp>), then the latest picture of that CLUT stream will be applied to the remaining frames of the <code class="code">mandelbrot</code> stream. <h4 class="subsubsection">11.118.2.2 Hald CLUT with preview# TOC</h4>

A Hald CLUT is supposed to be a squared image of <code class="code">Level*Level*Level</code> by <code class="code">Level*Level*Level</code> pixels. For a given Hald CLUT, FFmpeg will select the biggest possible square starting at the top left of the picture. The remaining padding pixels (bottom or right) will be ignored. This area can be used to add a preview of the Hald CLUT. Typically, the following generated Hald CLUT will be supported by the <code class="code">haldclut</code> filter: <pre class="example-preformatted">ffmpeg -f lavfi -i haldclutsrc=8 -vf " pad=iw+320 [padded_clut]; smptebars=s=320x256, split [a][b]; [padded_clut][a] overlay=W-320:h, curves=color_negative [main]; [main][b] overlay=W-320" -frames:v 1 clut.png </pre>

It contains the original and a preview of the effect of the CLUT: SMPTE color bars are displayed on the right-top, and below the same color bars processed by the color changes. Then, the effect of this Hald CLUT

can be visualized with: <pre class="example-preformatted">ffplay input.mkv -vf "movie=clut.png, [in] haldclut" </pre>

 <h3 class="section">11.119 hflip# TOC</h3>

Flip the input video horizontally. For example, to horizontally flip the input video with <code class="command">ffmpeg</code>: <pre class="example-preformatted">ffmpeg -i in.avi -vf "hflip" out.avi </pre>

 <h3 class="section">11.120 histeq# TOC</h3> This filter applies a global color histogram equalization on a per-frame basis. It can be used to correct video that has a compressed range of pixel intensities. The filter redistributes the pixel intensities to equalize their distribution across the intensity range. It may be viewed as an "automatically adjusting contrast filter". This filter is useful only for correcting degraded or poorly captured source video. The filter accepts the following options: <dl class="table"> <dt><samp class="option">strength</samp></dt> <dd> Determine the amount of equalization to be applied. As the strength is reduced, the distribution of pixel intensities more-and-more approaches that of the input frame. The value must be a float number in the range [0,1] and defaults to 0.200. </dd> <dt><samp class="option">intensity</samp></dt> <dd> Set the maximum intensity that can generated and scale the output values appropriately. The strength should be set as desired and then the intensity can be limited if needed to avoid washing-out. The value must be a float number in the range [0,1] and defaults to 0.210. </dd> <dt><samp class="option">antibanding</samp></dt> <dd> Set the antibanding level. If enabled the filter will randomly vary the luminance of output pixels by a small amount to avoid banding of the histogram. Possible values are <code class="code">none</code>, <code class="code">weak</code> or <code class="code">strong</code>. It defaults to <code class="code">none</code>. </dd> </dl>

 <h3 class="section">11.121 histogram# TOC</h3>

Compute and draw a color distribution histogram for the input video. The computed histogram is a representation of the color component distribution in an image. Standard histogram displays the color components distribution in an image. Displays color graph for

each color component. Shows distribution of the Y, U, V, A or R, G, B components, depending on input format, in the current frame. Below each graph a color component scale meter is shown. The filter accepts the following options: <dl class="table"> <dt><samp class="option">level_height</samp></dt> <dd> Set height of level. Default value is <code class="code">200</code>. Allowed range is [50, 2048]. </dd> <dt><samp class="option">scale_height</samp></dt> <dd> Set height of color scale. Default value is <code class="code">12</code>. Allowed range is [0, 40]. </dd> <dt><samp class="option">display_mode</samp></dt> <dd> Set display mode. It accepts the following values: <dl class="table"> <dt>‘<samp class="samp">stack</samp>’</dt> <dd> Per color component graphs are placed below each other. </dd> <dt>‘<samp class="samp">parade</samp>’</dt> <dd> Per color component graphs are placed side by side. </dd> <dt>‘<samp class="samp">overlay</samp>’</dt> <dd> Presents information identical to that in the <code class="code">parade</code>, except that the graphs representing color components are superimposed directly over one another. </dd> </dl> Default is <code class="code">stack</code>. </dd> <dt><samp class="option">levels_mode</samp></dt> <dd> Set mode. Can be either <code class="code">linear</code>, or <code class="code">logarithmic</code>. Default is <code class="code">linear</code>. </dd> <dt><samp class="option">components</samp></dt> <dd> Set what color components to display. Default is <code class="code">7</code>. </dd> <dt><samp class="option">fgopacity</samp></dt> <dd> Set foreground opacity. Default is <code class="code">0.7</code>. </dd> <dt><samp class="option">bgopacity</samp></dt> <dd> Set background opacity. Default is <code class="code">0.5</code>. </dd> <dt><samp class="option">colors_mode</samp></dt> <dd> Set colors mode. Examples-89” aria-hidden=”true”>TOC</h4>

<ul class=”itemize mark-bullet”> Calculate and draw histogram: <pre class=”example-preformatted”>ffplay -i input -vf histogram </pre>

 <h3 class=”section”>11.122 hqdn3d# TOC</h3>

This is a high precision/quality 3d denoise filter. It aims to reduce image noise, producing smooth images and making still images really still. It should enhance compressibility. It accepts the following optional parameters: <dl class=”table”> <dt><samp class=”option”>luma_spatial</samp></dt> <dd> A non-negative floating point number which specifies spatial luma strength. It defaults to 4.0. </dd> <dt><samp class=”option”>chroma_spatial</samp></dt> <dd> A non-negative floating point number which specifies spatial chroma strength. It defaults to 3.0*<var class=”var”>luma_spatial</var>/4.0. </dd> <dt><samp class=”option”>luma_tmp</samp></dt> <dd> A floating point number which specifies luma temporal strength. It defaults to 6.0*<var class=”var”>luma_spatial</var>/4.0. </dd> <dt><samp class=”option”>chroma_tmp</samp></dt> <dd> A floating point number which specifies chroma temporal strength. It defaults to <var class=”var”>luma_tmp</var>*<var class=”var”>chroma_spatial</var>/<var class=”var”>luma_spatial</var>. </dd> </dl>

 <h4 class=”subsection”>11.122.1 Commands# TOC</h4> This filter supports same commands as options. The command accepts the same syntax of the corresponding option. If the specified expression is not valid, it is kept at its current value. <h3 class=”section”>11.123 hwdownload# TOC</h3>

Download hardware frames to system memory. The input must be in hardware frames, and the output a non-hardware format. Not all formats will be supported on the output - it may be necessary to insert an additional <samp class=”option”>format</samp> filter immediately following in the graph to get the output in a supported format. <h3 class=”section”>11.124 hwmap<a class=”anchor hidden-xs” href=”#hwmap” aria-

hidden=”true”># TOC</h3>

Map hardware frames to system memory or to another device. This filter has several different modes of operation; which one is used depends on the input and output formats: <ul class=”itemize mark-bullet”> Hardware frame input, normal frame output

Map the input frames to system memory and pass them to the output. If the original hardware frame is later required (for example, after overlaying something else on part of it), the <samp class=”option”>hwmap</samp> filter can be used again in the next mode to retrieve it. Normal frame input, hardware frame output

If the input is actually a software-mapped hardware frame, then unmap it - that is, return the original hardware frame. Otherwise, a device must be provided. Create new hardware surfaces on that device for the output, then map them back to the software format at the input and give those frames to the preceding filter. This will then act like the <samp class=”option”>hwupload</samp> filter, but may be able to avoid an additional copy when the input is already in a compatible format. Hardware frame input and output

A device must be supplied for the output, either directly or with the <samp class=”option”>derive_device</samp> option. The input and output devices must be of different types and compatible - the exact meaning of this is system-dependent, but typically it means that they must refer to the same underlying hardware context (for example, refer to the same graphics card). If the input frames were originally created on the output device, then unmap to retrieve the original frames. Otherwise, map the frames to the output device - create new hardware frames on the output corresponding to the frames on the input.

The following additional parameters are accepted: <dl class=”table”> <dt><samp class=”option”>mode</samp></dt> <dd> Set the frame mapping mode. Some combination of: <dl class=”table”> <dt><var class=”var”>read</var></dt> <dd> The mapped frame should be readable. </dd> <dt><var class=”var”>write</var></dt> <dd> The mapped frame should be writeable. </dd> <dt><var class=”var”>overwrite</var></dt> <dd> The mapping will always overwrite the entire frame. This may improve performance in some cases, as the original contents of the frame need not be loaded. </dd> <dt><var class=”var”>direct</var></dt> <dd> The mapping must not involve any copying. Indirect mappings to copies of frames are created in some cases where either direct mapping is not possible or it would have unexpected properties. Setting this flag ensures that the mapping is direct and will fail if that is not possible. </dd> </dl> Defaults to <var class=”var”>read+write</var>

if not specified. </dd> <dt><samp class="option">derive_device <var class="var">type</var></samp></dt> <dd> Rather than using the device supplied at initialisation, instead derive a new device of type <var class="var">type</var> from the device the input frames exist on. </dd> <dt><samp class="option">reverse</samp></dt> <dd> In a hardware to hardware mapping, map in reverse - create frames in the sink and map them back to the source. This may be necessary in some cases where a mapping in one direction is required but only the opposite direction is supported by the devices being used. This option is dangerous - it may break the preceding filter in undefined ways if there are any additional constraints on that filter’s output. Do not use it without fully understanding the implications of its use. </dd> </dl>

 <h3 class="section">11.125 hwupload# TOC</h3>

Upload system memory frames to hardware surfaces. The device to upload to must be supplied when the filter is initialised. If using ffmpeg, select the appropriate device with the <samp class="option">-filter_hw_device</samp> option or with the <samp class="option">derive_device</samp> option. The input and output devices must be of different types and compatible - the exact meaning of this is system-dependent, but typically it means that they must refer to the same underlying hardware context (for example, refer to the same graphics card). The following additional parameters are accepted: <dl class="table"> <dt><samp class="option">derive_device <var class="var">type</var></samp></dt> <dd> Rather than using the device supplied at initialisation, instead derive a new device of type <var class="var">type</var> from the device the input frames exist on. </dd> </dl>

Grow first stream into second stream by connecting components. This makes it possible to build more robust edge masks. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>planes</samp></dt> <dd> Set which planes will be processed as bitmap, unprocessed planes will be copied from first stream. By default value 0xf, all planes will be processed. </dd> <dt><samp class=”option”>threshold</samp></dt> <dd> Set threshold which is used in filtering. If pixel component value is higher than this value filter algorithm for connecting components is activated. By default value is 0. </dd> </dl>

The <code class=”code”>hysteresis</code> filter also supports the framesync options. <h3 class=”section”>11.134 iccdetect# TOC</h3>

Detect the colorspace from an embedded ICC profile (if present), and update the frame’s tags accordingly. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>force</samp></dt> <dd> If true, the frame’s existing colorspace tags will always be overridden by values detected from an ICC profile. Otherwise, they will only be assigned if they contain <code class=”code”>unknown</code>. Enabled by default. </dd> </dl>

 <h3 class=”section”>11.135 iccgen# TOC</h3>

Generate ICC profiles and attach them to frames. This filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>color_primaries</samp></dt> <dt><samp class=”option”>color_trc</samp></dt> <dd> Configure the colorspace that the ICC profile will be generated for. The default value of <code class=”code”>auto</code> infers the value from the input frame’s metadata, defaulting to BT.709/sRGB as appropriate. See the setparams filter for a list of possible values, but note that <code class=”code”>unknown</code> are not valid values for this filter. </dd> <dt><samp class=”option”>force</samp></dt> <dd> If true, an ICC profile will be generated even if it would overwrite an already existing ICC profile. Disabled by default. </dd> </dl>

 <h3 class=”section”>11.136 identity# <a class=”anchor hidden-xs”href=”#toc-identity”

aria-hidden=”true”>TOC</h3>

Obtain the identity score between two input videos. This filter takes two input videos. Both input videos must have the same resolution and pixel format for this filter to work correctly. Also it assumes that both inputs have the same number of frames, which are compared one by one. The obtained per component, average, min and max identity score is printed through the logging system. The filter stores the calculated identity scores of each frame in frame metadata. This filter also supports the framesync options. In the below example the input file <samp class=”file”>main.mpg</samp> being processed is compared with the reference file <samp class=”file”>ref.mpg</samp>.   <pre class=”example-preformatted”>ffmpeg -i main.mpg -i ref.mpg -lavfi identity -f null - </pre>

 <h3 class=”section”>11.137 idet# TOC</h3>

Detect video interlacing type. This filter tries to detect if the input frames are interlaced, progressive, top or bottom field first. It will also try to detect fields that are repeated between adjacent frames (a sign of telecine). Single frame detection considers only immediately adjacent frames when classifying each frame. Multiple frame detection incorporates the classification history of previous frames. The filter will log these metadata values: <dl class=”table”> <dt><samp class=”option”>single.current_frame</samp></dt> <dd> Detected type of current frame using single-frame detection. One of: “tff” (top field first), “bff” (bottom field first), “progressive”, or “undetermined” </dd> <dt><samp class=”option”>single.tff</samp></dt> <dd> Cumulative number of frames detected as top field first using single-frame detection. </dd> <dt><samp class=”option”>multiple.tff</samp></dt> <dd> Cumulative number of frames detected as top field first using multiple-frame detection. </dd> <dt><samp class=”option”>single.bff</samp></dt> <dd> Cumulative number of frames detected as bottom field first using single-frame detection. </dd> <dt><samp class=”option”>multiple.current_frame</samp></dt> <dd> Detected type of current frame using multiple-frame detection. One of: “tff” (top field first), “bff” (bottom field first), “progressive”, or “undetermined” </dd> <dt><samp class=”option”>multiple.bff</samp></dt> <dd> Cumulative number of frames detected as bottom field first using multiple-frame detection. </dd> <dt><samp class=”option”>single.progressive</samp></dt> <dd> Cumulative number of frames detected as progressive using single-frame detection. </dd> <dt><samp class=”option”>multiple.progressive</samp></dt> <dd> Cumulative number of frames detected as progressive using multiple-frame detection. </dd> <dt><samp class=”option”>single.undetermined</samp></dt> <dd> Cumulative number of frames that could not be classified using single-

frame detection. </dd> <dt><samp class=”option”>multiple.undetermined</samp></dt>
<dd> Cumulative number of frames that could not be classified using multiple-frame detection. </dd> <dt><samp class=”option”>repeated.current_frame</samp></dt>
<dd> Which field in the current frame is repeated from the last. One of “neither”, “top”, or “bottom”. </dd> <dt><samp class=”option”>repeated.neither</samp></dt>
<dd> Cumulative number of frames with no repeated field. </dd>
<dt><samp class=”option”>repeated.top</samp></dt> <dd> Cumulative number of frames with the top field repeated from the previous frame’s top field. </dd> <dt><samp class=”option”>repeated.bottom</samp></dt>
<dd> Cumulative number of frames with the bottom field repeated from the previous frame’s bottom field. </dd> </dl>

The filter accepts the following options: <dl class=”table”>
<dt><samp class=”option”>intl_thres</samp></dt> <dd> Set interlacing threshold. </dd> <dt><samp class=”option”>prog_thres</samp></dt>
<dd> Set progressive threshold. </dd> <dt><samp class=”option”>rep_thres</samp></dt>
<dd> Threshold for repeated field detection. </dd> <dt><samp class=”option”>half_life</samp></dt> <dd> Number of frames after which a given frame’s contribution to the statistics is halved (i.e., it contributes only 0.5 to its classification). The default of 0 means that all frames seen are given full weight of 1.0 forever. </dd> <dt><samp class=”option”>analyze_interlaced_flag</samp></dt> <dd> When this is not 0 then idet will use the specified number of frames to determine if the interlaced flag is accurate, it will not count undetermined frames. If the flag is found to be accurate it will be used without any further computations, if it is found to be inaccurate it will be cleared without any further computations. This allows inserting the idet filter as a low computational method to clean up the interlaced flag </dd> </dl>

 <h4 class=”subsection”>11.137.1 Examples# TOC</h4>

Inspect the field order of the first 360 frames in a video, in verbose detail: <pre class=”example-preformatted”>ffmpeg -i INPUT -filter:v idet,metadata=mode=print -frames:v 360 -an -f null -
</pre> The idet filter will add analysis metadata to each frame, which will then be discarded. At the end, the filter will also print a final report with statistics. <h3 class=”section”>11.138 il# TOC</h3>

Deinterleave or interleave fields. This filter allows one to process interlaced images fields without deinterlacing them. Deinterleaving splits the input frame into 2 fields (so called half pictures). Odd lines

are moved to the top half of the output image, even lines to the bottom half. You can process (filter) them independently and then re-interleave them. The filter accepts the following options: <dl class="table"> <dt><samp class="option">luma_mode, l</samp></dt> <dt><samp class="option">chroma_mode, c</samp></dt> <dt><samp class="option">alpha_mode, a</samp></dt> <dd> Available values for <var class="var">luma_mode</var>, <var class="var">chroma_mode</var> and <var class="var">alpha_mode</var> are: <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dd> Do nothing. </dd> <dt>‘<samp class="samp">deinterleave, d</samp>’</dt> <dd> Deinterleave fields, placing one above the other. </dd> <dt>‘<samp class="samp">interleave, i</samp>’</dt> <dd> Interleave fields. Reverse the effect of deinterleaving. </dd> </dl> Default value is <code class="code">none</code>. </dd> <dt><samp class="option">luma_swap, ls</samp></dt> <dt><samp class="option">chroma_swap, cs</samp></dt> <dt><samp class="option">alpha_swap, as</samp></dt> <dd> Swap luma/chroma/alpha fields. Exchange even & odd lines. Default value is <code class="code">0</code>. </dd> </dl>

 <h4 class="subsection">11.138.1 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class="section">11.139 inflate# TOC</h3>

Apply inflate effect to the video. This filter replaces the pixel by the local(3x3) average by taking into account only values higher than the pixel. 104" aria-hidden="true"># TOC</h4>

This filter supports the all above options as commands. <h3 class="section">11.144 latticepal# TOC</h3>

Convert packed RGB/BGR input to PAL8 with a per-frame palette whose colors are placed on a face-centered cubic (FCC) lattice spanning the RGB cube. Each frame gets its own palette, built only from the lattice colors actually used by that frame. If a frame uses more than 256 lattice colors, they are reduced by iteratively dropping the color whose removal has the least impact (its pixel count times the squared distance to the nearest remaining color) and mapping its pixels to that nearest remaining color. The alpha channel, if present, is ignored unless the <samp class="option">alpha</samp> option is set. The filter accepts the following options: <dl class="table"> <dt><samp class="option">density</samp></dt> <dd> Set the lattice density as the number of lattice steps spanning one color axis (0 to 255). Higher values give a finer lattice and thus more possible colors, making it more likely that the per-frame color reduction has to drop some of them. At a density of <code class="code">7</code> with 256 palette entries no reduction ever happens since the whole lattice then holds exactly 256 points. Allowed range is <code class="code">1</code> to <code class="code">255</code>. Default is <code class="code">20</code>. </dd> <dt><samp class="option">max_colors</samp></dt> <dd> Set the maximum number of palette entries to use. Frames using more lattice colors than this are reduced accordingly. Allowed range is <code class="code">2</code> to <code class="code">256</code>. Default is <code class="code">256</code>. </dd> <dt><samp class="option">alpha</samp></dt> <dd> Quantize the alpha channel too, placing the palette colors on a 4 dimensional D4 lattice over RGBA instead of the FCC lattice over RGB. Inputs without an alpha channel are treated as opaque. With this option the density is limited to <code class="code">64</code>. Default is <code class="code">0</code> (alpha is ignored and the palette is fully opaque). </dd> <dt><samp class="option">refine</samp></dt> <dd> Redistribute the error introduced by dropping colors, which is otherwise uncompensated and can show as discolored patches. Frames that needed no reduction are not changed by this option. <dl class="table"> <dt>‘<samp class="samp">none</samp>’</dt> <dd> No refinement. </dd> <dt>‘<samp class="samp">full</samp>’</dt> <dd> Run a Floyd-Steinberg error diffusion pass over the whole frame against the final palette. Most accurate on average, but redithers everything, including regions whose colors survived. </dd> <dt>‘<samp class="samp">residual</samp>’</dt>

<dd> Diffuse only the residual between each pixel’s first pass quantized color and its final palette color. Pixels of surviving colors that receive no residual are unchanged, keeping the character of the selected dither mode outside the reduced regions. </dd> <dt>‘<samp class="samp">batched</samp>’</dt> <dd> Interleave color removal and rediffusion: drop half of the excess colors, rediffuse the whole frame against the survivors, recount the colors from the actual assignments and repeat. Colors that the dithering can reproduce by mixing become free to drop while extreme colors keep their pixels and are protected; this gives the best quality at the cost of about log2 of the number of dropped colors rediffusion passes. </dd> </dl>

Default is <code class="code">none</code>. </dd> <dt><samp class="option">dither</samp></dt> <dd> Select the dithering mode.  <h3 class="section">11.145 lenscorrection# TOC</h3>

Correct radial lens distortion This filter can be used to correct for radial distortion as can result from the use of wide angle lenses, and thereby re-rectify the image. To find the right parameters one can use tools available for example as part of opencv or simply trial-and-error. To use opencv use the calibration sample (under samples/cpp) from the opencv sources and extract the k1 and k2 coefficients from the resulting matrix. Note that effectively the same filter is available in the open-source tools Krita and Digikam from the KDE project. In contrast to the vignette filter, which can also be used to compensate lens errors, this filter corrects the distortion of the image, whereas vignette corrects the brightness distribution, so you may want to use both filters together in certain cases, though you will have to take care of ordering, i.e. whether vignetting should be applied before or after lens correction. <h4 class="subsection">11.145.1 Options<span

class=”pull-right”># TOC</h4>

The filter accepts the following options: <dl class=”table”> <dt><samp class=”option”>cx</samp></dt> <dd> Relative x-coordinate of the focal point of the image, and thereby the center of the distortion. This value has a range [0,1] and is expressed as fractions of the image width. Default is 0.5. </dd> <dt><samp class=”option”>cy</samp></dt> <dd> Relative y-coordinate of the focal point of the image, and thereby the center of the distortion. This value has a range [0,1] and is expressed as fractions of the image height. Default is 0.5. </dd> <dt><samp class=”option”>k1</samp></dt> <dd> Coefficient of the quadratic correction term. This value has a range [-1,1]. 0 means no correction. Default is 0. </dd> <dt><samp class=”option”>k2</samp></dt> <dd> Coefficient of the double quadratic correction term. This value has a range [-1,1]. 0 means no correction. Default is 0. </dd> <dt><samp class=”option”>i</samp></dt> <dd> Set interpolation type. Can be <code class=”code”>nearest</code> or <code class=”code”>bilinear</code>. Default is <code class=”code”>nearest</code>. </dd> <dt><samp class=”option”>fc</samp></dt> <dd> Specify the color of the unmapped pixels. For the syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. Default color is <code class=”code”>black@0</code>. </dd> </dl>

The formula that generates the correction is: <var class=”var”>r_src</var> = <var class=”var”>r_tgt</var> * (1 + <var class=”var”>k1</var> * (<var class=”var”>r_tgt</var> / <var class=”var”>r_0</var>)^2 + <var class=”var”>k2</var> * (<var class=”var”>r_tgt</var> / <var class=”var”>r_0</var>)^4) where <var class=”var”>r_0</var> is halve of the image diagonal and <var class=”var”>r_src</var> and <var class=”var”>r_tgt</var> are the distances from the focal point in the source and target images, respectively. <h4 class=”subsection”>11.145.2 Commands# TOC</h4>

This filter supports the all above options as commands. <h3 class=”section”>11.146 lensfun# TOC</h3>

Apply lens correction via the lensfun library (<a class=”url” href=”http://lensfun.sourceforge.net/”>http:/

The <code class=”code”>lensfun</code> filter requires the camera make, camera model, and lens model

to apply the lens correction. The filter will load the lensfun database and

query it to find the corresponding camera and lens entries in the database. As

long as these entries can be found with the given options, the filter can

perform corrections on frames. Note that incomplete strings will result in the

filter choosing the best match with the given options, and the filter will

output the chosen camera and lens models (logged with level "info"). You must

provide the make, camera model, and lens model as they are required.

To obtain a list of available makes and models, leave out one or both of <code class=”code”>make</code> and

<code class=”code”>model</code> options. The filter will send the full list to the log with level <code class=”code”>INFO</code>.

The first column is the make and the second column is the model.

To obtain a list of available lenses, set any values for make and model and leave out the

<code class=”code”>lens_model</code> option. The filter will send the full list of lenses in the log with level

<code class=”code”>INFO</code>. The ffmpeg tool will exit after the list is printed.

The filter accepts the following options:

<dl class=”table”>

<dt><samp class=”option”>make</samp></dt>

<dd> The make of the camera (for example, "Canon"). This option is required.

</dd>

<dt><samp class=”option”>model</samp></dt>

<dd> The model of the camera (for example, "Canon EOS 100D"). This option is

required.

</dd>

<dt><samp class=”option”>lens_model</samp></dt>

<dd> The model of the lens (for example, "Canon EF-S 18-55mm f/3.5-5.6 IS STM"). This

option is required.

</dd>

<dt><samp class=”option”>db_path</samp></dt>

<dd> The full path to the lens database folder. If not set, the filter will attempt to

load the database from the install path when the library was built. Default is unset.

</dd>

<dt><samp class=”option”>mode</samp></dt>

<dd> The type of correction to apply. The following values are valid options:

<dl class=”table”>

<dt>‘<samp class=”samp”>vignetting</samp>’</dt>

<dd> Enables fixing lens vignetting.

</dd>

<dt>‘<samp class=”samp”>geometry</samp>’</dt>

<dd> Enables fixing lens geometry. This is the default.

</dd>

<dt>‘<samp class=”samp”>subpixel</samp>’</dt>

<dd> Enables fixing chromatic aberrations.

</dd>

<dt>‘<samp class="samp">vig_geo</samp>’</dt>

<dd> Enables fixing lens vignetting and lens geometry.

</dd>

<dt>‘<samp class="samp">vig_subpixel</samp>’</dt>

<dd> Enables fixing lens vignetting and chromatic aberrations.

</dd>

<dt>‘<samp class="samp">distortion</samp>’</dt>

<dd> Enables fixing both lens geometry and chromatic aberrations.

</dd>

<dt>‘<samp class="samp">all</samp>’</dt>

<dd> Enables all possible corrections.

</dd>

</dl>

</dd>

<dt><samp class="option">focal_length</samp></dt>

<dd> The focal length of the image/video (zoom; expected constant for video). For

example, a 18–55mm lens has focal length range of [18–55], so a value in that

range should be chosen when using that lens. Default 18.

</dd>

<dt><samp class="option">aperture</samp></dt>

<dd> The aperture of the image/video (expected constant for video). Note that

aperture is only used for vignetting correction. Default 3.5.

</dd>

<dt><samp class="option">focus_distance</samp></dt>

<dd> The focus distance of the image/video (expected constant for video). Note that

focus distance is only used for vignetting and only slightly affects the

vignetting correction process. If unknown, leave it at the default value (which

is 1000).

</dd>

<dt><samp class="option">scale</samp></dt>

<dd> The scale factor which is applied after transformation. After correction the

video is no longer necessarily rectangular. This parameter controls how much of

the resulting image is visible. The value 0 means that a value will be chosen

automatically such that there is little or no unmapped area in the output

image. 1.0 means that no additional scaling is done. Lower values may result

in more of the corrected image being visible, while higher values may avoid

unmapped areas in the output.

</dd>

<dt><samp class="option">target_geometry</samp></dt>

<dd> The target geometry of the output image/video. The following values are valid

options:

<dl class="table">

<dt>‘<samp class="samp">rectilinear (default)</samp>’</dt>

<dt>‘<samp class="samp">fisheye</samp>’</dt>

<dt>‘<samp class="samp">panoramic</samp>’</dt>

<dt>‘<samp class="samp">equirectangular</samp>’</dt>

<dt>‘<samp class="samp">fisheye_orthographic</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_stereographic</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_equisolid</samp>’</dt>

<dt>‘<samp class=”samp”>fisheye_thoby</samp>’</dt>

</dl>

</dd>

<dt><samp class=”option”>reverse</samp></dt>

<dd> Apply the reverse of image correction (instead of correcting distortion, apply

it).

</dd>

<dt><samp class=”option”>interpolation</samp></dt>

<dd> The type of interpolation used when correcting distortion. The following values

are valid options:

<dl class=”table”>

<dt>‘<samp class=”samp”>nearest</samp>’</dt>

<dt>‘<samp class=”samp”>linear (default)</samp>’</dt>

<dt>‘<samp class=”samp”>lanczos</samp>’</dt>

</dl>

</dd>

</dl>

 <h4 class=”subsection”>11.146.1 Examples# TOC</h4>

<ul class=”itemize mark-bullet”> Apply lens correction with make "Canon", camera model "Canon EOS 100D", and lens model "Canon EF-S 18-55mm f/3.5-5.6 IS STM" with focal length of "18" and aperture of "8.0".

 <pre class=”example-preformatted”>ffmpeg -i input.mov -vf lensfun=make=Canon:model="Canon EOS 100D":lens_model="Canon

EF-S 18-55mm f/3.5-5.6 IS STM":focal_length=18:aperture=8 -c:v h264
-b:v 8000k output.mov </pre>

Apply the same as before, but only for the first 5 seconds of video.

 <pre class="example-preformatted">ffmpeg -i in-
put.mov -vf lensfun=make=Canon:model="Canon EOS 100D":lens_model="Canon
EF-S 18-55mm f/3.5-5.6 IS STM":focal_length=18:aperture=8:enable='lte(t\,5)'

Flexible GPU-accelerated processing filter based on libplacebo (<a
class="url" href="https://code.videolan.org/videolan/libplacebo">https://code.videolan.org/videolan/libplac
  <h4 class="subsection">11.148.1 Op-
tions<a class="anchor hidden-xs" href="#Options-
1" aria-hidden="true"># <a class="anchor hidden-xs"href="#toc-
Options-1" aria-hidden="true">TOC</h4>

The options for this filter are divided into the following sections: <a
name="Output-mode"> <h4 class="subsubsection">11.148.1.1 Output
mode<a class="anchor hidden-xs" href="#Output-
mode" aria-hidden="true"># <a class="anchor hidden-xs"href="#toc-
Output-mode" aria-hidden="true">TOC</h4> These
options control the overall output mode. By default, libplacebo will try
to preserve the source colorimetry and size as best as it can, but it will
apply any embedded film grain, dolby vision metadata or anamorphic
SAR present in source frames. <dl class="table"> <dt><samp
class="option">inputs</samp></dt> <dd> Set the number of in-
puts. This can be used, alongside the <code class="code">idx</code>
variable, to allow placing/blending multiple inputs inside the output
frame. This effectively enables functionality similar to <a class="ref"
href="#hstack">hstack, overlay,
etc. </dd> <dt><samp class="option">w</samp></dt>
<dt><samp class="option">h</samp></dt> <dd> Set the output
video dimension expression. Default values are <code class="code">iw</code>
and <code class="code">ih</code>. Allows for the same ex-
pressions as the scale filter.

</dd> <dt><samp class="option">crop_x</samp></dt> <dt><samp class="option">crop_y</samp></dt> <dd> Set the input crop x/y expressions, default values are <code class="code">(iw-cw)/2</code> and <code class="code">(ih-ch)/2</code>. </dd> <dt><samp class="option">crop_w</samp></dt> <dt><samp class="option">crop_h</samp></dt> <dd> Set the input crop width/height expressions, default values are <code class="code">iw</code> and <code class="code">ih</code>. </dd> <dt><samp class="option">pos_x</samp></dt> <dt><samp class="option">pos_y</samp></dt> <dd> Set the output placement x/y expressions, default values are <code class="code">(ow-pw)/2</code> and <code class="code">(oh-ph)/2</code>. </dd> <dt><samp class="option">pos_w</samp></dt> <dt><samp class="option">pos_h</samp></dt> <dd> Set the output placement width/height expressions, default values are <code class="code">ow</code> and <code class="code">oh</code>. </dd> <dt><samp class="option">rotate</samp></dt> <dd> Rotate the input frame clockwise by the specified angle. <dl class="table"> <dt>‘<samp class="samp">0, 360</samp>’</dt> <dt>‘<samp class="samp">90</samp>’</dt> <dt>‘<samp class="samp">180</samp>’</dt> <dt>‘<samp class="samp">270</samp>’</dt> </dl>

</dd> <dt><samp class="option">fps</samp></dt> <dd> Set the output frame rate. This can be rational, e.g. <code class="code">60000/1001</code>. If set to the special string <code class="code">none</code> (the default), input timestamps will instead be passed through to the output unmodified. Otherwise, the input video frames will be interpolated as necessary to rescale the video to the specified target framerate, in a manner as determined by the <samp class="option">frame_mixer</samp> option. </dd> <dt><samp class="option">format</samp></dt> <dd> Set the output format override. If unset (the default), frames will be output in the same format as the respective input frames. Otherwise, format conversion will be performed. </dd> <dt><samp class="option">force_original_aspect_ratio</samp></dt> <dt><samp class="option">force_divisible_by</samp></dt> <dd> Work the same as the identical scale filter options. Note that <samp class="option">force_divisible_by</samp> also works with <code class="code">fit_sense=constraint</code>. </dd> <dt><samp class="option">reset_sar</samp></dt> <dd> If enabled, output frames will always have a pixel aspect ratio of 1:1. If disabled (the default), any aspect ratio mismatches, including those from e.g. anamorphic video sources, are forwarded to the output pixel aspect ratio. </dd> <dt><samp class="option">normalize_sar</samp></dt> <dd> Like <samp class="option">reset_sar</samp>, but instead of stretching the video content to fill the new output aspect ratio, the content is instead padded or cropped as necessary. Mutually exclusive with <samp class="option">fit_mode</samp>. Disabled by default.

 </dd> <dt><samp class="option">pad_crop_ratio</samp></dt> <dd> Specifies a ratio (between <code class="code">0.0</code> and <code class="code">1.0</code>) between padding and cropping when the input aspect ratio does not match the output aspect ratio and <samp class="option">normalize_sar</samp> is in effect. The default of <code class="code">0.0</code> always pads the content with black borders, while a value of <code class="code">1.0</code> always crops off parts of the content. Intermediate values are possible, leading to a mix of the two approaches. </dd> <dt><samp class="option">fit_mode</samp></dt> <dd> Specify the content fit strategy according to a list of predefined modes. Determines how the input image is to be placed inside the destination crop rectangle (as defined by <code class="code">pos_x/y</code> and <code class="code">pos_w/h</code>). The names and their implementations are taken from the CSS ’object-fit’ property. Note that this option is mutually exclusive with <samp class="option">normalize_sar</samp>. Defaults to <code class="code">fill</code>. Valid values are: <dl class="table"> <dt>‘<samp class="samp">fill</samp>’</dt> <dd> Stretch the input to the output rectangle, ignoring aspect ratio mismatches. Note that unless <samp class="option">reset_sar</samp> is also enabled, the output will still have the correct pixel aspect ratio tagged. </dd> <dt>‘<samp class="samp">contain</samp>’</dt> <dd> Scale the input to fit inside the output, preserving aspect ratio by padding. Equivalent to <samp class="option">normalize_sar</samp> with <samp class="option">pad_crop_ratio</samp> set to <code class="code">0.0</code>. </dd> <dt>‘<samp class="samp">cover</samp>’</dt> <dd> Scale the input to fill the output, preserving aspect ratio by cropping. Equivalent to <samp class="option">normalize_sar</samp> with <samp class="option">pad_crop_ratio</samp> set to <code class="code">1.0</code>. </dd> <dt>‘<samp class="samp">none, place</samp>’</dt> <dd> Don’t scale the input. The input will be placed inside the output rectangle at its natural size; which may result in additional padding or cropping. </dd> <dt>‘<samp class="samp">scale_down</samp>’</dt> <dd> Scale the input down as much as needed to fit inside the output. Equivalent to either <code class="code">contain</code> or <code class="code">none</code>, depending on whether the input is larger than the output or not. </dd> </dl>

</dd> <dt><samp class="option">fit_sense</samp></dt> <dd> When <samp class="option">fit_mode</samp> is in use, this option controls how the fit strategy is applied against the specified output resolution. Mutually exclusive with <samp class="option">force_original_aspect_ratio</samp>. Valid values are: <dl class="table"> <dt>‘<samp class="samp">target</samp>’</dt> <dd> The computed output resolution is taken as the exact size of the output frame. This is the default behavior. </dd> <dt>‘<samp

class=”samp”>constraint</samp>’</dt> <dd> The computed output resolution is a size reference against which the fit mode is applied, enlarging or decreasing the true frame size as needed to fit the content. </dd> </dl>

</dd> <dt><samp class=”option”>fillcolor</samp></dt> <dd> Set the color used to fill the output area not covered by the output image, for example as a result of <samp class=”option”>normalize_sar</samp>. For the general syntax of this option, check the <a data-manual=”ffmpeg-utils” href=”./ffmpeg-utils.html#color-syntax”>"Color" section in the ffmpeg-utils manual. Defaults to <code class=”code”>black@0</code>. </dd> <dt><samp class=”option”>corner_rounding</samp></dt> <dd> Render frames with rounded corners. The value, given as a float ranging from <code class=”code”>0.0</code> to <code class=”code”>1.0</code>, indicates the relative degree of rounding, from fully square to fully circular. In other words, it gives the radius divided by half the smaller side length. Defaults to <code class=”code”>0.0</code>. </dd> <dt><samp class=”option”>lut</samp></dt> <dd> Specifies a custom LUT (in Adobe .cube format) to apply to the colors as part of color conversion. The exact interpretation depends on the value of <samp class=”option”>lut_type</samp>. </dd> <dt><samp class=”option”>lut_type</samp></dt> <dd> Controls the interpretation of color values fed to and from the LUT specified as <samp class=”option”>lut</samp>. Valid values are: <dl class=”table”> <dt>‘<samp class=”samp”>auto</samp>’</dt> <dd> Chooses the interpretation of the LUT automatically from tagged metadata, and otherwise falls back to ‘<samp class=”samp”>native</samp>’. (Default) </dd> <dt>‘<samp class=”samp”>native</samp>’</dt> <dd> Applied to raw image contents in its native RGB colorspace (nonlinear light), before conversion to the output color space. </dd> <dt>‘<samp class=”samp”>normalized</samp>’</dt> <dd> Applied to the normalized RGB image contents, in linear light, before conversion to the output color space. </dd> <dt>‘<samp class=”samp”>conversion</samp>’</dt> <dd> Fully replaces the conversion from the image color space to the output color space. If such a LUT is present, it has the highest priority, and overrides any ICC profiles, as well as options related to tone mapping and output colorimetry (<samp class=”option”>color_primaries</samp>, <samp class=”option”>color_trc</samp>). </dd> </dl>

</dd> <dt><samp class=”option”>extra_opts</samp></dt> <dd> Pass extra libplacebo internal configuration options. These can be specified as a list of <var class=”var”>key</var>=<var class=”var”>value</var> pairs separated by ’:’. The following example shows how to configure a custom filter kernel ("EWA LanczosSharp") and use it to double the input image resolution: <pre class=”example-preformatted”>-vf "libplacebo=w=iw*2:h=ih*2:extra_opts='upscaler=custom\:upscaler_preset=ewa_

</pre>

</dd> <dt><samp class=”option”>shader_cache</samp></dt> <dd> File path of a cache directory that libplacebo will use to store and load cached shader objects. This cache is not cleaned up automatically. If the path does not end in a directory separator, the generated filenames will be effectively prefixed by the last path component. All directories must already exist.   <pre class=”example-preformatted”>-vf "libplacebo=shader_cache=/tmp/pl-shader-" </pre>

</dd> <dt><samp class=”option”>inherit_device</samp></dt> <dd> Take the Vulkan device from the hardware frames arriving on the input, instead of creating a private one from the filter’s own hardware device. This is useful when the input frames originate on another API (for example CUDA frames uploaded to Vulkan by <code class=”code”>hwupload</code>) and the filter’s device is not itself a Vulkan device: libplacebo would otherwise spin up a separate Vulkan device that the input frames do not belong to, and the frames could not be mapped. When enabled, the filter requires Vulkan hardware frames on the input and will fail negotiation otherwise. Disabled by default.   <pre class=”example-preformatted”>-init_hw_device vulkan=vk:0 -init_hw_device cuda@vk -filter_hw_device cuda0 ... -vf "hwupload=derive_device=vulkan,libplacebo=inherit_device=1" </pre>

</dd> <dt><samp class=”option”>colorspace</samp></dt> <dt><samp class=”option”>color_primaries</samp></dt> <dt><samp class=”option”>color_trc</samp></dt> <dt><samp class=”option”>range</samp></dt> <dt><samp class=”option”>chroma_location</samp><
<dd> Configure the colorspace that output frames will be delivered in. For any value other than the default <code class=”code”>auto</code>, conversion will be performed. With <code class=”code”>auto</code>, <samp class=”option”>color_primaries</samp> and <samp class=”option”>color_trc</samp> keep the values of the input frames, while <samp class=”option”>colorspace</samp>, <samp class=”option”>range</samp> and <samp class=”option”>chroma_location</samp> use the values negotiated with the filtergraph, which are those of the input unless a following filter requires others. See the setparams filter for a list of possible values. </dd> <dt><samp class=”option”>alpha_mode</samp></dt> <dd> Choose the desired output alpha mode, when the output format has an alpha channel. See the setparams filter for a list of possible values. </dd> <dt><samp class=”option”>apply_filmgrain</samp></dt> <dd> Apply film grain (e.g. AV1 or H.274) if present in source frames, and strip it from the output. Enabled by default. </dd> <dt><samp class=”option”>apply_dolbyvision</samp></dt> <dd> Apply Dolby Vision RPU metadata if present in source frames, and strip it from the output. Enabled by default. Note that Dolby Vision will always output BT.2020+PQ, overriding the usual input frame metadata. These will also be picked as the

values of <code class="code">auto</code> for the respective frame output options. </dd> </dl>
